Ministry of Disaster Management and Relief (MoDMR)

Atlas
Seismic Risk Assessment in Bangladesh
for Bogra, Dinajpur, Mymensingh, Rajshahi, Rangpur and Tangail
City Corporation / Paurashava Areas, Bangladesh
Unlike most natural disasters prediction of earthquake is very complex. It requires highly technical and sophisticated knowledge gathered through scientific research. Due to the geological set up Bangladesh is under tremendous threat of impending devastating earthquake that could be generated from any of the regional active faults, located within the country and/or its immediate vicinity. Rapidly growing of urban population, proliferation of high density unplanned urban agglomerations and, improper designed and poorly constructed urban dwellings and infrastructure are having compounding effects on the urban disaster vulnerability landscape to a great extent. In the backdrop of such a situation, it is a very timely initiative by Comprehensive Disaster Management Programme (CDMP II), a programme of Ministry of Disaster Management and Relief, to commission earthquake risk assessment of major cities and paurashavas of Bangladesh and publishing this Atlas on "Seismic Risk Assessment of Bangladesh" compiling outputs of the assessments undertaken in this regard.

In Bangladesh our response towards any imminent earthquake disaster mainly would be to increase our preparedness to a level so that vulnerabilities of city dwellers and city infrastructure are reduced, and resilience of individuals, communities and above all local government institutions are increased. These can be achieved through information sharing, awareness raising and capacity building of relevant institutions.

CDMP's investment in generating scientific information on earthquake risk assessment had been substantial over the years and the sheer amount of information generated had been tremendous. This Atlas, a compiled handy form of information generated, could be used for ready references in decision making, planning and designing of risk reduction interventions, in scientific research, in city and infrastructure management, and above all in the awareness building of city dwellers. All of these would lead to the building of resilient urban space and also of resilient urban communities.

I would like to take this opportunity to thank both national and international professionals who worked relentlessly to publish this very valuable document for the country

Md. Shah Kamal
Secretary
Ministry of Disaster Management and Relief (MoDMR)
Empowered lives. Resilient nations.

Message

Bangladesh’s rapid urbanization and steady progress towards middle-income-country status means that today, more than ever, the resilience of the country’s urban centers is vital to the continued well-being of its people and its continued development. It is therefore with great pleasure that I welcome the publication of this atlas of seismic risk assessment in Bangladesh. This atlas presents extensive and detailed data on earthquake hazards, risks and vulnerabilities of six major cities and municipalities. It is the product of a risk research and assessment effort as-yet unparalleled in Bangladesh, providing a thorough and detailed knowledge base for both decision-making and future research and updates.

Having not only enough, but also the right type of knowledge is crucial in securing the lives and livelihoods of people residing in disaster-prone areas. The relative infrequency of earthquakes makes it hard for those who have not the lived experience or specialist expertise to make the right decisions. Having a repository of data and knowledge should enable Bangladesh to not only ‘build back better’ in the event of an earthquake – but to be able to build better in the first place. The results from the technical and multi-disciplinary research – including studies of seismic fault lines, geological and structural vulnerabilities – presented in this atlas create a strong basis to develop key policy instruments and demonstrate the need for urgent implementation of these. I hope that this atlas will be actively and frequently consulted by decision-makers, becoming a resource not only to disaster risk reduction professionals, but also to local government officials, development professionals, planners, and researchers across the board.

The publication of this atlas is an achievement that would not have been possible without the support, participation and dedication of the Ministry of Disaster Management and Relief, the Comprehensive Disaster Management Program team, and numerous national and international experts and professionals.

I extend my heartfelt congratulations and thanks to all those who have contributed to the extensive process of gathering, assessing and presenting the data in this atlas. The hard work of all the contributors will benefit decision makers, professionals, and most importantly – the people of Bangladesh for years to come.

Pauline Tamesis
Country Director
UNDP Bangladesh
It is really very pleasing to know that Comprehensive Disaster Management Programme (CDMP II), has taken initiative to publish an Atlas on “Seismic Risk Assessment in Bangladesh” compiling results of the assessments undertaken in 6 major cities and paurashavas of Bangladesh. This is in fact the first of its kind in Bangladesh produced from very comprehensive scientific studies conducted over last four years.

Bangladesh is an earthquake prone country, due its proximity to major regional faults and underlying physical, social and economic vulnerabilities. Risk of any impending earthquake is increasing for the urban centers of the country in every passing moment. Taking appropriate preparedness measures to minimize the devastating effects of any impending earthquake is high on the agenda of the Government of Bangladesh. However, in designing and implementing appropriate interventions on earthquake risk reduction the necessity of having scientific information had been a long overdue. CDMP’s current initiative of publishing this atlas therefore could be viewed as a right step towards a right direction.

Department of Disaster Management is one of the implementing arms of the Ministry of Disaster Management and Relief for dealing with disaster management activities in Bangladesh. The department has a network of professionals working across the country. This very important knowledge product will definitely help its professionals to take risk informed decisions in their everyday businesses. Besides, since DDM is the safe depository of disaster management related knowledge products and documents, and, is the institutional memory for MoDMR, this valuable document will be an important inclusion which could be used for a ready reference for the researchers and professionals.

I would encourage planners, development professionals and all concerned citizens to make best use of this atlas, so that, working together we can make our cities and towns more resilient.

I express my heartfelt thanks to UNDP and other development partners for supporting CDMP II to conduct various high quality studies, and specially, on earthquake risk assessment of 6 very vulnerable cities and paurashavas of Bangladesh and to publish this very valuable Atlas.

Md. Reaz Ahmed
Director General (Additional Secretary)
Department of Disaster Management (DDM)
Bangladesh is recognized as one of the most vulnerable countries of the world with regard to earthquake disaster due to its geographical location, unabated and unplanned growth of urban settlements and infrastructure, and ever increasing urban population. Current trend of urbanisation is likely to increase earthquake vulnerability of the country, specifically to major urban centers, located very close to the major active faults of the region to many folds.

Comprehensive Disaster Management Programme of Ministry of Disaster Management and Relief for the first time in the country initiated comprehensive earthquake risk assessment during its phase I and continued the endeavor in phase II which is designed and being implemented to reduce Urban Disaster Risks. A wide range of high quality scientific studies, including earthquake Hazard Identification, Risk and Vulnerability Assessment, Risk Informed Landuse and Contingency Planning have been conducted by the eminent national and international professionals, and well reputed agencies from home and abroad. The Atlas on “Seismic Risk Assessment in Bangladesh” for 6 highly vulnerable cities/paurashavas of Bangladesh is a consolidated output of all these efforts.

The Atlas has been developed with the intention of assisting the policy makers, government officials, planners working in various Ministries and Departments, academicians and researchers, house owners and developers to understand the earthquake vulnerabilities of respective cities and paurashavas of the country, which would enable them to take risk informed decisions for planning, designing and constructing urban infrastructure to reduce urban disaster risk to a great extent.

I firmly believe this Atlas would contribute immensely to the existing national knowledge pool on seismic hazard and related vulnerabilities in Bangladesh. Besides, at practitioners’ level it would help in taking pro-active and targeted preparedness initiatives, which are needed to achieve our much cherished dream of ‘paradigm shift’ (from response to risk reduction) in disaster management of the country.

I congratulate the professionals working in CDMP and other agencies for the sincere efforts they put together for publishing this Atlas.

Mohammad Abdul Qayyum
Additional Secretary &
National Project Director
Comprehensive Disaster Management Programme (CDMP II)
ACKNOWLEDGEMENT

Comprehensive Disaster Management Programme II (CDMP II) acknowledges the contribution and wonderful spirit of cooperation from all concerned strategic partners of CDMP II, particularly the Asian Disaster Preparedness Center (ADPC) for the successful completion of the Atlas on “Seismic Risk Assessment in Bangladesh” describing the underlying threat, vulnerability, risk and potential damage due to earthquake in Rajshahi, Rangpur city corporation and Bogra, Dinajpur, Mymensingh, and Tangail Paurashava areas.

Special thanks are due to Mohammad Abdul Qayyum, Additional Secretary and the National Project Director of CDMP II, and, the Urban Risk Reduction Team of CDMP II for their continuous following up, guidance and advice to ensure that the Atlas is of a high standard.

The Atlas development process was inspired by MoDMR. Continuous encouragement from UNDP had always been there. Technical guidance from the Technical Advisory Group, and contribution of a good number of national and international professionals, who worked hard on the assignment, had been very instrumental in the development and publishing of this Atlas, and, is appreciated. CDMP II also recognizes the contribution and support from respective City Corporations and Paurashavas.

It is important to note that this Atlas is a living document, and, therefore, there is an expectation of further improvement in future based on continuous research in many relevant disciplines.

It is now hoped and expected that intended end user of the atlas, the planners, engineers and developers, working in these six cities will apply the knowledge in pursuit of a safer Bangladesh.

Peter Medway
Project Manager
Comprehensive Disaster Management Programme (CDMP II)
Urbanization has a great influence on the role disaster risk plays across the world. In the low and lower-middle income countries, new urban development is increasingly more likely to occur on hazard prone land, namely, in floodplains and other low-lying areas, along fault lines, and on steep slopes. In addition to settling in hazard prone areas, much of the building construction that occurs is unregulated and unplanned, placing vulnerable populations, who settle on hazard prone land, at increased risk. Bangladesh is no exception to these trends. Since the country is projected to experience rapid urbanization over the next several decades, it is imperative for the policy makers and urban managers to plan for new urban developments with proper integration of disaster risk information and pertinent risk management options into the urban planning and construction processes.

In recent years, Bangladesh has made significant progress in integrating flood risk management in both physical and social development initiatives. There is however, increasing disaster risk from other impending hazards like Earthquakes. Since most of the major cities in Bangladesh are growing rapidly without proper development control, the anticipated risk for the people and infrastructure are gradually increasing. In this context the MoDMR along with the project partners of CDMP II saw the need to develop a Seismic Risk Assessment for growing urban areas in Bangladesh. The project, Seismic Risk Assessment for the Six Major Cities and Municipalities (i.e. Bogra, Dinajpur, Mymensingh, Rajshahi, Rangpur and Tangail) in Bangladesh is the first major step towards identifying the potential earthquake risks for the major cities and devise possible planning and preparedness initiatives for Disaster Risk Reduction (DRR).

Current initiative of Seismic Risk Assessment includes scientific assessments of seismic hazard that is looming on to these cities, their vulnerabilities and risks, and above all, portraying of probable damage scenarios that could be experienced by these cities in case of any impending earthquake. State of the Art technologies and scientific methodologies have been used to assess the seismic hazard, vulnerabilities and risks of the cities and municipalities under the current project. In order to perform rigorous seismic hazard analysis, all available information of historical earthquakes, tectonic environment, and instrumental seismic data were gathered. In this study probabilistic assessment of two ground motion parameters, namely, horizontal Peak Ground Acceleration (PGA) and Spectral Acceleration (SA) values at 0.2s and 1.0s with return periods of 43, 475, and 2475 years were conducted. However, in this Atlas Scenario of 475 year return period, which is recommended as design base for National Building Code, is presented. A good number of geotechnical and geophysical investigations were conducted for preparation of Engineering Geological Map, Soil Liquefaction maps for seismic hazard assessment and for damage and loss estimation. The investigations include boreholes with SPT, PS Logging, MASW and SSM, Microtremor Array and Single Microtremor assessments.

Damage and risk assessment for seismic hazard provide forecasts of damage and human and economic impacts that may result from earthquake. Risk assessments of general building stock, essential facilities (hospitals, emergency operation centers, schools) and lifelines (transportation and utility systems) using the HAZUS software package were conducted in this study. HAZUS was developed by the United States' Federal Emergency Management Agency (FEMA) and National Institute of Building Sciences (NIBS). It is a powerful risk assessment software program for analyzing potential losses from disasters on a regional basis. For risk assessment analyses of the six City Corporation /Purashava areas, defaults databases for the United States were replaced with Bangladesh databases of the 6 cities/municipalities.
Reputed experts from both home and abroad, under the guidance of very well-known and revered group of professionals of the country in the Technical Advisory Group for the project, worked relentlessly for years to generate scientific information required for these assessments. Information generated were duly cross checked and scientifically verified.

This Atlas mainly presents the summary of the assessment findings of different components under the project. Main objective of the Atlas is to provide decision makers, and city planners and managers with a compiled and handy set of information on the current situation of the respective sectors in the cities in terms of vulnerability and risk to facilitate more informed and effective development decision making.

This atlas contains altogether 5 Chapters. Unlike traditional atlases, a brief description on natural disasters in Bangladesh and a general overview of disaster management of the country, discussed in chapter One would help readers to understand seismic risk assessment and management in context of entire gamut of disaster management of the country. Geological setting, seismic hazard and history of seismicity in Bangladesh issues described in chapter Two would provide readers with a clear view of seismic activities, their origins and hazard potentials in and around the country. Chapter Three, the major part of the atlas, presents seismic vulnerability and risk assessment results of 6 cities/municipalities along with a brief discussion on initiatives taken so far on seismic research in Bangladesh and methodology adopted in the current study for seismic hazard, vulnerability and risk assessment. Chapter Four presents different preparedness initiatives, like preparation of Spatial Contingency Plan, simulation drill, capacity building initiatives, so far been taken by the Government of Bangladesh. These would help raising awareness among local government officials, change agents, CBOs and the communities on preparedness initiatives and devising right kind of interventions to be taken for any impending seismic disaster. Chapter Five describes the way forward for future initiatives with regard to seismic preparedness for the country.

These assessment results included in the Atlas are expected to help in reducing underlying risk factors for these cities, in promoting the preparedness initiatives and enhancing emergency response capabilities of the key GOB organizations, humanitarian aid agencies, development partners, decision makers, and above all, in increasing awareness of city dwellers. The assessment results are expected to be further integrated into the physical planning process of these cities in future, and would also provide useful inputs into construction regulation and practices in order to develop risk resilient built environment. Along with this Atlas a good number of different reports have been produced under the current initiative of CDMP II. All these reports are available at e-library of CDMP II and available at its website (www.dmic.org.bd/e-library). Maps presented in this document can be used as reference only, for more detail, it is however, recommended to consult main reports.

SEISMIC RISK ASSESSMENT IN BANGLADESH
The project “Seismic Risk Assessment in Bangladesh” was initiated by the Comprehensive Disaster Management Programme (CDMP) under the Ministry of Disaster Management and Relief (MoDMR) of the Government of the Peoples' Republic of Bangladesh. The Programme is funded by the United Nations Development Program (UNDP), European Union (EU), Norwegian Embassy, UKaid, Swedish Sida and Australian Aid. The study was conducted in two phases, CDMP I (2007-2009) and CDMP II (2012-2014). In phase I seismic risk assessments were conducted for Dhaka, Chittagong and Sylhet city corporation areas, while in phase II assessments were conducted for Bogra, Dinajpur, Mymensingh, Rajshahi, Rangpur and Tangail city corporation/municipal areas.

The main objectives of the project has been to understand the prevailing earthquake hazard in the national context; to understand the vulnerability and risk related to earthquake in the major cities of the country; and to undertake initiatives for earthquake preparedness and capacity building in accordance with requirements at, National, City, Community and Agency levels. The project has specifically addressed the following issues:

- Earthquake hazard, vulnerability and risk assessment for the major cities in Bangladesh.
- Preparation of earthquake Contingency Plans for National, City, Agency and Community levels, based on scenarios developed from risk assessment results.
- Training and capacity building activities targeting groups like students and teachers, masons and bar binders, religious leaders, decision makers, and the first responding agencies in different cities in Bangladesh.
- Development of Risk Communication Strategies based on the risk assessment case studies, and implementation of these using modern technologies and approaches.

**PROJECT PARTNERS**

The Project was implemented by the Asian Disaster Preparedness Center (Center) Thailand in association with OYO International Corporation Japan, Asian Institute of Technology (AIT) Thailand, National Society for Earthquake Technology (NSET) Nepal and Data Experts Limited (datEx) Bangladesh. The project was also supported by the Department of Disaster Management (DDM), Geological Survey of Bangladesh (GSR), Urban Development Directorate (UDD), Bangladesh Fire Service and Civil Defense (BFSCD), Dhaka University, Bangladesh University of Engineering and Technology (BUET), Chittagong University of Engineering and Technology (CUET), Rajshahi University of Engineering and Technology (RUET), Dhaka North City Corporation (DNCC), Dhaka South City Corporation (DSCC), Chittagong City Corporation (CCC), Sylhet City Corporation (SCC), Rajshahi City Corporation (RCC), Rajshahi Development Authority (RDA), Rangpur City Corporation (RCC), Mymensingh Paurashava, Dinajpur Paurashava, Tangail Paurashava and Bogra Paurashava.
This Atlas contains basic information about the hazards and disaster management system in Bangladesh. The main focus of the atlas is the earthquake history of the country and the region, earthquake hazard in context of Bangladesh, and earthquake vulnerability and risk with regard to population, infrastructure, building stock, and emergency facilities in six major cities / Paurashavas (municipalities), including potential damage and loss estimation.

The main objective of the Atlas is to provide decision makers with information on the current situation of the respective sectors in the cities in terms of vulnerability and risk. The study on seismic hazard assessment considered Probabilistic Assessment in terms of PGA at 43, 475, and 2475 year return periods. Two scenarios have been developed for each of the return periods. However, in this Atlas, scenarios of a 475 year return period- recommended as design base under the Building Code- is also presented. Different types of exposure maps have been developed for all the cities included in the current assessment. Scenario maps (i.e., maps of likely concrete & masonry building damage, liquefaction susceptibility, likely infrastructure damage maps etc.) have been developed based on the risk assessment tools used in the assessment. Furthermore, the Atlas also contains a brief discussion of the different initiatives for earthquake risk reduction and enhancing earthquake disaster preparedness implemented as part of MoDRM’s CDMP II activities. Detailed methodology, discussions, results are available in the documents listed in Annex-2 Seismic Risk Assessment: Available Research Documents in Bangladesh.

This Atlas will assist the government departments in improving the Earthquake Risk Management system in their respective work areas. It will also provide useful input to the formulation of policies and regulations to relevant sectors and their proper implementation.

CHAPTER - 01
GENERAL INTRODUCTION
1.1 INTRODUCTION

Over the past decades, urbanization in Bangladesh has flourished without proper guidance. As a result, many urban centers have developed haphazardly. These urban centers are fast growing and influence the economic development of the country. It is therefore essential to have a realistic understanding of the nature, severity and likely damage/loss that an earthquake could cause in these urban areas. A strong earthquake affecting major urban centers may result in damage and destruction of massive proportions, with disastrous consequences for the entire nation.

Considering this reality, the Comprehensive Disaster Management Programme (CDMP) being implemented by the Ministry of Disaster Management and Relief (MoDMR) of the Government of Bangladesh (GoB) and supported by United Nations Development Program (UNDP), European Union (EU), Norwegian Embassy, UKaid from the Department for International Development (DFID), Swedish Sida and Australian Aid, is designed to strengthen the Bangladesh Disaster Management System, and more specifically, to achieve a paradigm shift from reactive response to a proactive risk reduction culture. As part of this, the Asian Disaster Preparedness Center (ADPC) has been given responsibility for conducting seismic risk assessments for several major cities in Bangladesh. This Atlas presents the seismic risk assessment of Bogra, Dinajpur, Mymensingh, Rajshahi, Rangpur and Tangail Municipal Areas. Chapter One describes the project background, and briefly discusses the natural disasters and disaster management system in Bangladesh. Chapter Two presents a seismic hazard assessment of the country, followed in Chapter Three by the seismic vulnerability, risk assessment methodology, different scenarios, and assessment results of different cities. The results of risk assessment include: direct earthquake damage, induced earthquake damage, casualties, and economic losses* to the components at risk. Chapter Four describes the preparedness initiatives implemented at different levels under this project. Chapter Five describes the way forward for seismic preparedness for Bangladesh.

1.2 BANGLADESH AND NATURAL DISASTER

Due to its location Bangladesh has to receive and drain out huge volume of upstream waters. The mighty rivers Meghna, Padma and Brahmaputra, originate in the Himalayas, make their way through Bangladesh, and drain in the Bay of Bengal. In the summer, from May to August, the melting of glaciers in the Himalayas makes the rivers in Bangladesh live. The rainy season, which is strongly influenced by monsoon wind from the South West, also sets in at the same causing massive precipitation. The combined effect of upstream flows, precipitation and terrestrial run-off result in flooding, causing water logging and prolonged flood almost every year.

![Figure 1: Intensity of floods in Bangladesh from 1954 to 1999 (Banglapedia, 2014)](image)

*economic losses due to scenario earthquake for different cities were developed under this project. Detail on this is available document [g] listed in Annex 2 Seismic Risk Assessment: Available Research Documents in Bangladesh
Furthermore, rising sea levels are causing water level rise in the river, thereby accelerating the risk of flood and water logging. As the elevation of the coastal plain of Bangladesh is only 3-5 meter from the mean sea level, a vast coastal area – approximately 18% of the total landmass of the country – would be submerged by a 1 meter sea level rise, according to the IPCC 4th Assessment Report (USA. IPCC, 2007). The main factors behind these assumptions are: a) the country has no defense mechanism for the protection of coastal plain land, and b) the sea level will rise following the contour line. The problem of water logging might be more dangerous than flooding. Already, many coastal places where sustainable drainage network system has not developed, are facing water logging problems, and the intensity of problem is becoming more catastrophic day by day.

**Figure 2: Bangladesh flood affected areas (Banglapedia, 2014)**

The entire coastal zone is prone to violent storms and tropical cyclones during pre-monsoon and post-monsoon season. Therefore, the Bangladesh coastal zone could be termed a geographical ‘death trap’ due to its extreme vulnerability to cyclones and storm surges. Since 1830, nearly one million people have been killed by cyclones in Bangladesh. Only 10 percent of the world’s cyclones develop in the Indian Ocean, but these 10 percent cause 85 percent of global cyclonic havoc (Gray, 1968).

The good news is that death tolls due to cyclones have decreased over the last decade, due to cyclone preparedness programs such as the mobilization of volunteers in disseminating cyclone warnings and information and the building of cyclone shelters. According to UNDP (2004) Bangladesh is among the Asian countries most highly prone to cyclonic disaster, as evident by the fact that out of the 350 thousand cyclone-cause deaths worldwide between 1986 to 2000, 60 percent were in Bangladesh. Even though
the Philippines is more vulnerable to cyclone than Bangladesh, the cyclonic death toll is 10 times higher in Bangladesh than in the Philippines.

Extreme and non-extreme weather or climate events can affect vulnerability to future extreme events by affecting resilience, coping capacity, and adaptive capacity (USA. IPCC, 2012). In particular, the cumulative effects of disasters at local or sub-national levels can substantially affect livelihood options, resources, and the capacity of societies and communities to prepare for and respond to future disasters.

A changing climate leads to changes in the frequency, intensity, spatial extent, duration, and timing of extreme weather and climate events, and can result in unprecedented extreme weather and climate events.
Landslides in the south eastern hilly region are another major hazard the country. These areas have a long history of geological instability. Although written records of landslide incidents are very rare, they have been a hazard to people ever since the area was first settled. Every year, especially in the rainy season, landslides take place in both natural and man-induced slopes. The cause is often infiltration of water which makes the swelling soils more fluid. Major processes that cause landslides in Bangladesh are 1) removal of lateral support through: (a) erosion by rivers, (b) previous slope movements such as slumps that create new slopes, (c) human modifications of slopes such as cuts, pits, and canals; 2) the addition of weight to the slope through: (a) accumulation of rain, (b) increase in vegetation, (c) construction of fill, (d) weight of buildings and other structures, (e) weight of water from leaking pipelines, sewers, canals, and reservoirs; 3) earthquakes; 4) regional tilting; 5) removal of underlying support through: (a) undercutting by rivers and waves; (b) swelling of clays; and 6) anthropogenic activities as jhum cultivation.

Drought- a prolonged, continuous period of dry weather along with abnormal insufficient rainfall- is also another frequent disaster in Bangladesh, especially in the north west region of the country. Drought occurs when evaporation and transpiration exceed the amount of precipitation for a reasonable period. It causes the earth to parch, as well as a considerable hydrologic (water) imbalance - resulting water shortages, dried-up wells, depletion of groundwater and soil moisture, stream flow reduction, crop withering and failing, and scarcity in fodder for livestock. Drought is a major natural hazard facing those communities that are directly dependent on rainfall for drinking water, crop production, and rearing of animals. Drought has become a recurrent natural phenomenon of northwestern Bangladesh (i.e. Rarind Tract) in recent decades. The Rarind Tract covers most parts of the greater Dinajpur, Rangpur, Pabna, Rajshahi, Bogra, Joypurhat and Naogaon districts of Rajshahi division. Rainfall is low in the Barind Tract compared to other parts of the country. The average rainfall is about 1,931 mm, the majority of which occurs during the monsoon. Rainfall varies as well as yearly. For instance, rainfall recorded in 1981 was about 1,738 mm, but in 1992 it was 798 mm. The distribution of rainfall is rather variable from one place to another. Thus, the region is already known as drought prone area. The average highest temperature of the Barind region ranges from 35°C to 25°C for the hottest season, and from 12°C to 15°C for the coolest season. Generally this particular region of the country is rather hot and can be considered a semi-arid region. In summer, the Rajshahi area, particularly Lalpur, may experience temperatures of about 45°C or even more on the hottest days. Meanwhile, in the winter the temperatures may even fall to 5°C in some places of Dinajpur and Rangpur districts. So this older alluvium region experiences two extremes that clearly contrast with the climatic condition of the rest of the country. Meteorologically drought can be classified into three types: permanent drought - characterized by arid climate; seasonal drought - caused by irregularities in recognized rainy and dry seasons; and contingent drought - caused by irregular rainfall. In Bangladesh, the last two types are more prevalent.

Drought mostly affects Bangladesh in the pre-monsoon and post-monsoon periods. While drought did not affect the entire country between 1949 and 1979, the percentage of drought affected areas were 31.63% in 1951, 46.54% in 1957, 37.47% in 1958, 33.93% in 1961, 18.42% in 1966, 42.48% in 1972 and 42.04% in 1979. During 1991 and 1992 droughts affected the production of the monsoon crops only. During the last 50 years, Bangladesh has suffered about 20 instances of drought conditions. Droughts in northwestern Bangladesh led to a shortfall of rice production of 3.5 million tons in the 1990s. If other losses, such as, to other crops (all rabi crops, sugarcane, wheat, etc.) as well as to perennial agricultural resources, such as, bamboo, betel nut, fruits like litchi, mango, jackfruit, banana etc. are considered, the loss is substantially much higher.
Earthquake refers to the trembling or shaking movement of the earth's surface. Most earthquakes are minor tremors, while larger earthquakes usually begin with slight tremors, rapidly take the form of one or more violent shocks, and end in vibrations of gradually diminishing force, called aftershocks. An earthquake is a form of energy in wave motions, which originates in a limited region and then spreads out in all directions from the source of disturbance. It usually lasts for a few seconds to a minute. Earthquakes happen due to a number of reasons, which can be divided into two major categories: non-tectonic and tectonic. Earthquakes are distributed unevenly on the globe. However, it has been observed that most of the destructive earthquakes originate within two well-defined zones or belts, namely ‘the circum-Pacific belt’ and ‘the Mediterranean-Himalayan seismic belt’.

Bangladesh is extremely vulnerable to seismic activity. Accurate historical information on earthquakes is very important in evaluating the seismicity of Bangladesh, especially in combination with assessment of the geotectonic elements. Information on earthquakes in and around Bangladesh is available for the last 250 years. The earthquake record suggests that since 1900, more than 100 moderate to large earthquakes occurred in Bangladesh, out of which more than 65 events occurred after 1960. This brings to light an increased frequency of earthquakes in the last 30 years. This increase in earthquake activity is an indication of fresh tectonic activity or propagation of fractures from the adjacent seismic zones. Details about earthquake in Bangladesh are described in Chapter 2.
1.3 Disaster Risk Management in Bangladesh

Due to its geographic location and dense settlement pattern, Bangladesh has a long history of being affected by natural disasters. It is estimated that between 1980 to 2008 the country faced damages of 16 Billion USD from about 200 disaster events. As a developing country, Bangladesh had to depend very much on relief from donor agencies and foreign countries. After a devastating flood in 1988, a national Flood Action Plan was initiated, marking the birth of a culture of disaster management and risk reduction. A catastrophic cyclone in 1991 demonstrated the necessity of establishing institutional disaster management platforms in the country, and consequently the Disaster Management Bureau (current DDM) was established in 1993. From the early 2000s, with a view to shifting from the traditional relief and rehabilitation approach to the more holistic disaster risk reduction approach, initiative was taken for a Comprehensive Disaster Management Program contributing to disaster preparedness at all levels of the country. Currently, the Ministry of Disaster Management and Relief of the Government of Bangladesh is the responsible ministry for coordinating national disaster management efforts across all agencies. The Ministry issued the Standing Orders on Disaster (SOD) in January 1997 (updated in 2010) to guide and monitor disaster management activities in Bangladesh.

![Disaster Management Regulatory Framework](image)

Figure 5: Disaster Management Regulatory Framework in Bangladesh (NPDM 2010-2015)
The main objective of the SOD is to make the concerned persons understand their duties and responsibilities regarding disaster management at all levels, enabling them to act accordingly. All Ministries, Divisions/Departments and Agencies shall prepare their own Action Plans with respect to their responsibilities under the Standing Orders for efficient implementation. The National Disaster Management Council (NDMC) and Inter-Ministerial Disaster Management Coordination Committee (IMDMCC) are to ensure coordination of disaster related activities at the National level. Coordination at District, Thana and Union levels are to be done by the respective District, Thana and Union Disaster Management Committees. The Department of Disaster Management is to render all assistance to them by facilitating the process (GoB. DDM, 2010).

Inter-related institutions, at both national and sub-national levels have been created to ensure effective planning and coordination of disaster risk reduction and emergency response management. Below is the list of the respective National and Sub-national level institutions:

**At National levels**

1. National Disaster Management Council (NDMC) headed by the Honorable Prime Minister to formulate and review the disaster management policies and issue directives to all concerns.

2. Inter-Ministerial Disaster Management Co-ordination Committee (IMDMCC) headed by the Hon'ble Minister in charge of the Disaster Management and Relief Division (DM&RD) to implement disaster management policies and decisions of NDMC / Government.

3. National Disaster Management Advisory Committee (NDMAC) headed by an experienced person nominated by the Honorable Prime Minister.

4. National Platform for Disaster Risk Reduction (NPDRR) headed by Secretary, DM&RD and DG, while DDM functions as the member secretary. This platform shall coordinate and provide necessary facilitation to the relevant stakeholders.

5. Earthquake Preparedness and Awareness Committee (EPAC) headed by Honorable minister for MoFDM and DG, DDM acts as member secretary.

6. Cyclone Preparedness Program Implementation Board (CPPIB) headed by the Secretary, Disaster Management and Relief to review the preparedness activities in the face of initial stages of impending cyclones.

7. Cyclone Preparedness Programme (CPP) Policy Committee headed by Honorable Minister, MoFDM and Secretary, DM&RD act as member secretary. Disaster Management Training and Public Awareness Building Task Force (DMTPATF) headed by the Director General of Department of Disaster Management (DDM) to coordinate the disaster related training and public awareness activities of the Government, NGOs and other organizations.

8. Focal Point Operation Coordination Group of Disaster Management (FPOCG) headed by the Director General of DDM to review and coordinate the activities of various departments/agencies related to disaster management and also to review the Contingency Plan prepared by concerned departments.

9. NGO Coordination Committee on Disaster Management (NGOCC) headed by the Director General of DDM to review and coordinate the activities of concerned NGOs in the country.

10. Committee for Speedy Dissemination of Disaster Related Warning/ Signals (CSDDWS) headed by the Director General of DDM to examine, ensure and find out the ways and means for the speedy dissemination of warning/ signals among the people.
At sub-national levels

1. District Disaster Management Committee (DDMC) headed by the Deputy Commissioner (DC) to coordinate and review the disaster management activities at the District level.

2. Upazila Disaster Management Committee (UDMC) headed by the Upazila Nirbahi Officer (UNO) to coordinate and review the disaster management activities at the Upazila level.

3. Union Disaster Management Committee (UDMC) headed by the Chairman of the Union Parishad to coordinate, review and implement the disaster management activities of the concerned Union.

4. Paurashava Disaster Management Committee (PDMC) headed by Chairman of Pourashova (Paurashava) to coordinate, review and implement the disaster management activities within its area of jurisdiction.

5. City Corporation Disaster Management Committee (CCDMC) headed by the Mayor of City Corporations to coordinate, review and implement the disaster management activities within its area of jurisdiction.

Earthquake Preparedness and Awareness Committee (EPAC)

Following the verdict of High Court Division of the Supreme Court of Bangladesh, dated 29 July 2009, the Government of Bangladesh has formed a committee on Earthquake Preparedness and Awareness, in order to prepare the nation for earthquake risk management (SOD, 2010). Following members constitute the Earthquake Preparedness and Awareness Committee:

- Minister, Ministry of Disaster Management and Relief (erstwhile MoFDM);
- Secretary, Ministry of Home Affairs;
- Secretary, Finance Division, Ministry of Finance;
- Secretary, Ministry of Disaster Management and Relief;
- Secretary, Roads and Railways Division;
- Secretary, Ministry of Information;
- Secretary, Ministry of Health and Family Planning Affairs;
- Secretary, Ministry of Defence;
- Secretary, Ministry of Foreign Affairs;
- Secretary, Economic Relations Divisions;
- Secretary, Housing and Public Works Ministry;
- Secretary, energy and Mineral Resource Division;
- Secretary, Ministry of Education;
➢ Secretary, Primary and Mass Education Ministry;

➢ Secretary, Local Government Division;

➢ Chief Engineer, Roads and Highways Department;

➢ Chief Engineer, Engineering Education Department;

➢ Chief Engineer, Local Government Engineering Department (LGED);

➢ Chief engineer, Public Works Department (PWD);

➢ Director General, Geological Survey of Bangladesh (GSB);

➢ Director General, Health Services;

➢ Director General, Fire Services and Civil Defence Department;

➢ Representative, Department of Geology, University of Dhaka;

➢ Representative, Department of Geography and Environment, Jahangirnagar University;

➢ Representative, Civil Engineering Department, BUET;

➢ Representative, Department of Geography and Environment, University of Chittagong;

➢ Representative, Civil and Environmental Engineering, SUST;

➢ Director, BMD;

➢ Director, Armed Forces Division (AFD);

➢ Chairman, Bangladesh Red Crescent Societies (BDRCS);

➢ Representative CARE;

➢ Representative Oxfam;

➢ Representative BRAC;

➢ Representative CARITAS;

➢ Representative Action Aid;

➢ Representative Save The Children USA;

➢ Representative World Vision;

➢ Representative Islamic Relief UK;
Director General, Department of Disaster Management (DDM) as member secretary.

The Committee is supposed to meet twice a year, and the Chairman may call additional meetings if necessary. Sub-committees may be formed for contingency planning and aspects of earthquake risk reduction. The responsibilities of the committee are:

1. Reviewing national earthquake preparedness and awareness programme and recommend suggestion for concerned organizations;

2. Reviewing the list of Search and Rescue equipment for earthquakes;

3. Preparing and recommending a list of equipment for earthquake risk reduction and search and rescue programmes after an earthquake.
CHAPTER - 02

SEISMIC HAZARD IN BANGLADESH
2.1 Geological Settings

Tectonically, Bangladesh lies on the northeastern Indian plate, near the edge of the Indian craton and at the junction of three tectonic plates—the Indian plate, the Eurasian plate and the Burmese microplate. These form two boundaries where plates converge—the India Eurasia plate boundary to the north forming the Himalaya Arc, and the India Burma plate boundary to the east forming the Burma Arc. The Indian plate is moving at a rate of 6 cm per year in a northeast direction, and subducting under the Eurasian and the Burmese plates in the north and east, at a rate of 45 mm per year and 35 mm per year, respectively (Sella et al., 2002; Bilham, 2004; Akhter, 2010).

To the north, the collision between the Indian and Eurasian plates has created the spectacular Himalayan Mountains, bounded along their southern flank by the Himalayan Frontal Thrust (HFT), along which continental lithosphere of the Indian plate under thrusts the Eurasian plate. This great north dipping thrust fault runs more than 2,000 km from Pakistan to Assam and has produced many large continental earthquakes over the past millennium, some greater than M 8. The 500-km long section just 60 km north of Bangladesh, however, has not produced a great earthquake in the past several hundred years (Kumar et al. 2010).

The other major active tectonic belt of Bangladesh appears along the country's eastern side. The Arakan subduction-collision system involves oblique convergence of the Indian and Burmese plates. It has produced the N-S trending Indoburman range and a broad belt of folds along the western edge of the Bay of Bengal (Curray, 2005; Wang and Sieh, 2013). These lie above a mega thrust that dips moderately eastward beneath the Indoburman range but is nearly flat lying beneath the folds. Beneath the 500-km long fold belt the mega thrust is also referred to as a decollement, because it is parallel or nearly parallel to sediment bedding within the Ganges Brahmaputra delta. As we will describe below, many of the folds within the western 100 to 200 km of the fold belt appear to be actively growing, which implies that the underlying decollement is relaying slip onto thrust faults beneath these folds as it dies out westward toward a poorly defined deformation front.
2.2 Seismic Hazard and Bangladesh

Bangladesh is located in the tectonically active Himalayan orogenic belt, which has developed through the collision among the Indian, Arabian, and Eurasian plates over the last 30-40 million years (Ma) (Aitchinson et al. 2007). Moderate to large earthquake magnitudes are common in this region and will continue to occur as long as the tectonic deformation continues. Some of these earthquakes cause serious damage to buildings and infrastructures through strong ground shaking and also, in some cases, faults rupturing the ground surface. The destructive and deadly hazards associated with earthquakes pose a real and serious threat to the lives of people, property damage, economic growth and development of the country. A proper understanding of the distribution and level of seismic hazard throughout the country is therefore necessary. In order to perform rigorous seismic hazard analysis, all available knowledge of the historical earthquakes, the tectonic environment, and instrumental seismic data are required to predict the strong ground shaking of future earthquakes. However, until now, investigation of the seismic potential of Bangladesh’s tectonic elements has been in its infancy (GoB. CDMP, 2013). The main objective of this work is to determine appropriate earthquake ground motion parameters for seismic mitigation, based on current existing data and most recent geological data interpretation. These ground motion parameters include: horizontal Peak Ground Acceleration (PGA) and Spectral Acceleration (SA) values at 0.2 and 1.0 s with the return periods of 43, 475, and 2475 years.

The study team has considered Probabilistic Seismic Hazard Assessment in terms of PGA at 43, 475, and 2475 year return periods and Spectral Acceleration (SA) at 0.25 and 1.0 s at 43, 475, and 2475 year return periods. In general, at the short return period, i.e. 43 years, the observed seismicity in and around Bangladesh controls the hazard for most considered structural periods. However, at long return period, i.e. 2475 years, the seismic hazard of all structural period is controlled by major tectonic structures, and these results confirm the importance of further study of active tectonic structures in Bangladesh. For the 475 year return period PGA hazard map, the hazard is fairly well correlated with the seismicity pattern shown in figure 10a. The effect of major active tectonic structures in and around Bangladesh, excepting that from area near Dauki fault, on seismic hazard is not clear on this map.

Ground motion across Bangladesh (represented by PGA) is in the range of 0.1–0.6 g, corresponding to the 475 year return period and in the range of 0.1–1.0 g, corresponding to the 2475 year return period. The effect of the high-slip rate of Dauki fault could be observed as the largest seismic hazard zone in Bangladesh. From the PGA and SA at 0.25 and 1.0 s at 475 and 2475 year return period for six cities (i.e. Bogra, Dinajpur, Mymensingh, Rajshahi, Rangpur and Tangail), are included in CDMP phase II. Out of these six cities, Bogra, Mymensingh, and Rangpur have by far the greatest seismic hazard. The estimated PGA value of 0.5 g at 2475 year return period is comparable to the seismically active region of the intermountain west in the United States (Petersen et al., 2008). This is primarily due to its proximity to the potentially fast moving Dauki fault which augmented from high rate of background seismicity. The seismic hazard of Rajshahi is the lowest at about 0.4 g at 2475 year return period, largely because it is far removed from the Dauki active fault and Arakan blind mega thrust. In addition, Rajshahi is the one of location in Bangladesh where previous analysis – based on instrumental seismicity – may underestimate what might be expected from the Martin and Szeliga’s (2010) historical earthquake catalogue, where there are two events located with earthquake magnitude between 7.3 and 8.0 on 11 November 1842 and 22 June 1897, respectively.

## 2.3 History of Seismicity in Bangladesh

Although in the recent past Bangladesh has not been affected by any large earthquakes, the evidence of large scale earthquakes in the region serves as a reminder of the possibility of big earthquakes in the future. Past major earthquakes in and around Bangladesh include the 1548 earthquake that hit the Sylhet and Chittagong regions, the 1642 earthquake in Sylhet District with damage to building structures, 1762 earthquake hit most part of Bangladesh including Dhaka & Chittagong caused loss of life and properties, 1897 Known as the Great India Earthquake with a magnitude of 8.7 hit the region. This earthquake caused serious damage to buildings in Sylhet town, where the death toll rose to 545. In Mymensingh, many public buildings, including the Justice House, collapsed. Heavy damage was done to the bridges on the Dhaka - Mymensingh railway and traffic was suspended for about a fortnight. The river communication of the district was seriously affected. Loss of life was not great, but loss of property was estimated at five million Rupees. Rajshahi suffered severe shocks, especially on the eastern side, and 15 people died. In Dhaka, damage to property was heavy. In Tippora, masonry buildings and old temples suffered a lot and the total damage was estimated at Rs. 9,000. The 1918 earthquake known as the Srimangal Earthquake is occurred on 18 July with a magnitude of 7.6 Richter scale, its epicenter located at Srimangal, Maulvi Bazar.

![1897 Great Indian Earthquake, M=8.7](http://images.rgs.org and http://nisee.berkeley.edu)

**Figure 7: Effect of 1897 Great Indian Earthquake (Oldham and Richard, 1899, http://images.rgs.org and http://nisee.berkeley.edu)**

- Rail Track at Rangpur
- Damage at Rangpur, 1897 earthquake
- Court - Kachari Building
- Collapse of building in Armanitola Dhaka
- Damage at Sirajganj - 1897 Earthquake

**Figure 8: Effect of 1997 Earthquake, Bangladesh (Al-Hussaini, 2005)**
The 1997 Chittagong earthquake, or the 1997 Bandarban earthquake, occurred on November 21, 1997 at 11:23 UTC in the Bangladesh-India-Myanmar border region. It had a magnitude of Mw 6.1 (USGS, 2014). The epicenter was located in southern Mizoram, India. While no fatalities were reported in Mizoram, India, however, 23 people were killed when a 5-storey building collapsed in Chittagong, Bangladesh (ASC, 2008).

An earthquake occurred on 22 July, 1999 at Maheshkhali Island with the epicenter in the same place, a magnitude of 5.2. The earthquake was severely felt around Maheshkhali Island and the adjoining sea. Houses cracked and in some cases collapsed.

The Borkol earthquake occurred in the early morning of 27 July 2003 at 5:18:37.96 am local time, killed three people, injured 25 people and damaged about 500 buildings in Chittagong and the Chittagong Hill Tracts. Power supply to some areas was cut as a transformer exploded at the Modunaghat Grid Sub-station in Hathazari, Chittagong. The epicenter was situated 217 km southeast of Dhaka at the eastern bank of Kaptai reservoir. It had a magnitude measured Mw 5.2. Dhaka shook with MM intensity IV. Many people were awakened, especially residents of upper floors of high rise buildings.
Seismic Hazard Map of Different Return Periods

The study team has considered Probabilistic Seismic Hazard Assessment* of second para of section 2.2.

*Please refer figure 10 (a) - (f) on Seismic Hazard Map of Different Return Periods. Detail Methodology on return period calculation is available in reference document [f] listed in Annex - 3 Seismic Risk Assessment: Available Research Documents in Bangladesh.
CHAPTER - 03

SEISMIC VULNERABILITY AND RISK ASSESSMENT INITIATIVES IN BANGLADESH
3.1 Initiatives for Seismic Preparedness in Bangladesh

Recognizing the earthquake vulnerability and risk in Bangladesh, a number of initiatives have been taken by the Government, research institutes, donor agencies, International NGOs and National NGOs regarding Earthquake Preparedness and Management. Most of the initiated projects are focusing in three thematic areas like Hazard & Risk Assessment, Awareness & Capacity Building and Formulation of Plan & Preparedness. Following is a brief overview of the activities initiated by different agencies in these different areas of earthquake preparedness and management.

Hazard & Risk Assessment and Research

Department of Disaster Management (DDM), under the ministry of Disaster Management and Relief, is the focal agency in Bangladesh for Disaster Risk Reduction and Disaster Risk Management. Since its inception in 1993 DDM has taken several initiatives for Disaster Management Activities. Currently DDM (2011-2015) is implementing a project named "Multi Hazard Risk and Vulnerability Assessment and Mapping" for the whole country. This nationwide assessment will cover the hazards like flood, earthquake, drought, cyclone, storm surge etc. The assessment would act as the guidance for the disaster preparedness initiatives in Bangladesh. The hazard and vulnerability mapping will be updated with the course of time and will be useful for the emergency preparedness guide.

The Geological Survey of Bangladesh (GSB), under Ministry of Energy and Mineral Resources of the Government of Bangladesh, plays vital role in earthquake research across the country. The main activities of the organization are to deal with the technical and scientific aspects of earthquake. As a part of that, the GSB check the land formation change, changes in river courses, undulation in land etc. immediately after any earthquake. Earthquake fault zones are also identified by the Geological Survey of Bangladesh as a part of its regular activities.

As a part of earthquake preparedness, GSB has installed Earthquake accelerometer at 20 points across the country. The reading of these stations is useful for building code revision in the context of different parts of the country. In the recent time, GSB has conducted geological investigation at Purbachal and Jhilmil residential areas. These results of the investigation will be handed over to the respective agency which can be used for building code implementation in these areas.

Comprehensive Disaster Management Programme (CDMP) under the ministry of Disaster Management and Relief has launched major earthquake preparedness programs in Bangladesh. The initiatives started in 2008 with the earthquake risk assessment of Dhaka, Chittagong and Sylhet City Corporation areas. This earthquake assessment also identified the active faults across the country that is the sources for major possible earthquake. CDMP II also initiated for (2012-2014) earthquake risk assessment, training & awareness development and city, agency and ward level Contingency Plan preparation for the cities of Bogra, Dinajpur, Mymensingh, Rajshahi, Rangpur and Tangail.
Chittagong Hill Tracts Development Facilities (CHTDF)-UNDP is a special program for the three hill districts of Bangladesh. Under one of the regional programs, named ECRRP, CHTDF-UNDP took the initiative to conduct earth hazard and risk assessment for the paurashavas of Rangamati, Bandarban and Khagrachari. The project was implemented from 2009 to 2010. Under this initiative, detailed base maps, seismic hazard maps, building and lifeline vulnerability assessments were made for the municipal towns of Rangamati, Bandarban and Khagrachari. During the implementation of the project, a number of professionals from these three towns were also provided with training on earthquake risk assessment methodology and techniques.

Bangladesh University of Engineering and Technology (BUET) have had several earthquake preparedness and research studies over the years. The research projects include Seismic Micro Zonation in Cox’s Bazar, a School Safety program in Dhaka and organizing trainings on doing earthquake research. Additionally, the Civil Engineering Department of the institute has enhanced its capacity through earthquake research programs initiated over the years. Moreover, the Bangladesh Network for Urban Safety (BNUS) was initiated by BUET with the collaboration from ICUS, Japan. BUET also has expertise in structural engineering, geotechnical engineering, and preparation of seismic hazard maps and in seismic micro-zonation of urban areas in Bangladesh. It has already established the National Centre for Earthquake Engineering (NCEE) in 2002. BUET is currently overseeing a seismic instrumentation project for a five kilometer long bridge (Jamuna multipurpose bridge, Bangladesh). It has also procured sixty SMAs from USGS recently. A two year linkage project with Virginia Polytech Institute and State University, USA, on the topic of the seismic vulnerability of Bangladesh, has been established.

The Earth observatory under the Department of Geology, University of Dhaka (established in 2003) is working with scientific research on geological setup and tectonic setting. Currently, the center has 23 GPS units to monitor the 3D movement of the earth crust. Active fault study and mapping is one of the primary subjects the center wishes to emphasize in its activities in the near future.
3.2 RISK ASSESSMENT PROCESS AND METHODOLOGY

The seismic risk assessment describes the scale and the extent of damage and disruption that may result from potential earthquakes. Damage and risk assessments for seismic hazards provide forecasts of damage, and human and economic impacts that may result from earthquake. The scope of work covers the risk assessment of the general building stock, essential facilities (hospitals, emergency operation centers, schools) and lifelines (transportation and utility systems). For CDMP-I & CDMP II the risk assessment has been executed using the HAZUS software package. HAZUS was developed by the United States’ Federal Emergency Management Agency (FEMA) and the National Institute of Building Sciences (NIBS). It is a powerful risk assessment software program for analyzing potential losses from disasters on a regional basis. This risk assessment scheme can be used primarily by local, regional, and central government officials to plan and stimulate efforts to reduce risks from earthquakes and to prepare for emergency response and recovery.

HAZUS operates through a Geographic Information System (GIS) application i.e. the ESRI ArcGIS platform. For risk assessment analyses of the nine city corporation areas and paurashavas, defaults databases for the United States have been replaced with Bangladesh databases of the nine cities/towns. Ground shaking is characterized quantitatively, using peak ground accelerations and spectral response accelerations. HAZUS methodology aggregates the general building stocks on a cluster basis, but is site-specific for essential facilities and lifelines. The transportation and utility lifeline losses are combined in one package with losses associated with the general building stock and essential facilities.

The framework of the HAZUS risk assessment methodology includes six major modules shown in Figure 11. As indicated by the arrows in the figure, the modules are interdependent, with the output of one module acting as input to another. Explanation of every module is given below.

---

**Figure 11: Flowchart of HAZUS Earthquake Risk Assessment Methodology**
1. Potential Earth Science Hazards (PESH)

The PESH module estimates ground motion and ground failure. Ground motion demands such as Peak Ground Acceleration (PGA) and spectral acceleration are estimated based on earthquake source parameters, attenuation relations and geological data. Ground failure caused by landslides, liquefaction and surface fault rupture are quantified by Permanent Ground Deformation (PGD). This PGD is determined based on topographic data, geological data and ground water depth.

2. Inventory

The inventory contains tools for describing the physical infrastructure and demographics of the study areas. It uses standardized classification systems for the groups of components at risk: (a) general building stock, (b) essential facilities, (c) transportation system components, and (d) utility system components. These groups are defined to address distinct inventory and modeling characteristics. An extensive amount of GIS database is utilized to develop dataset for each these groups.

The general building stock is classified by occupancy (residential, commercial, etc.) and by model building type (structural system and material, height). Characteristic relationships between occupancy and structure types are developed based on building survey data. Population data is derived from the average of building occupants per unit building, which is obtained from the building survey. Estimates for building exposure are based on building replacement costs (dollars per square foot) for each model building type and occupancy class that has been modified to Bangladesh cost. The dataset of essential facilities lifelines is developed from the GIS database and secondary sources (service provider authority), clarified and verified through the field survey.

3. Direct Physical Damage

This module provides damage estimates in terms of probabilities of occurrence for specific damage states given in a specified level of ground motion and ground failure. Estimates also include loss of function to essential facilities and lifelines and the anticipated service outages for potable water and electric power.

For buildings, the capacity-demand spectrum method as implied by HAZUS is utilized for the estimation of seismic demand. The estimated seismic demand is, thus, used to determine the probability of being in a particular damage state through fragility functions. However, the seismic performance of buildings in Bangladesh is different from that of United States. As a result, a new set of building capacity spectrum and fragility functions were developed based on the field survey data and comprehensive numerical analyses.

For both essential facilities and general building stock, damage state probabilities are determined for each facility or structural class. Damage is expressed in terms of probabilities of occurrence of specific damage states, given specific levels of ground motion and ground failure. Five damage states are identified - none, slight, moderate, extensive and complete.

For lifeline components, the methodology focuses on estimating damage and restoration times for every system of transportation (highway, railway, bus, and ferry) and utility (potable water, waste water, natural gas, electric power, communication). Overall fragility curves for a system are evaluated, using fault tree logic to combine components fragility curves. The hazard is typically represented by Peak Ground Acceleration (PGA) and Permanent Ground Deformation (PGD). Utilizing overall fragility curves, damage state probabilities are calculated for the lifeline components. Restoration times are evaluated from very simplified rules, relating to degree of damage and size of component.
4. Induced Physical Damage

Once direct physical damage has been calculated, induced damage can be evaluated. Induced damage is defined as the secondary consequences of a natural hazard other than damage due to the primary hazard (earthquake) that led to initial losses. Here, the methodology calculates damage due to fire following an earthquake and tonnage of debris generation. For estimation of the impacts from the fires that follow an earthquake, HAZUS methodology utilizes Monte Carlo simulation techniques to assess the potential impacts. It separates the module into 3 major elements: fire ignition, spread, and suppression. The number of fires ignited is estimated from the size and type of building inventory, and the ground motion to which it is subjected. Spread is calculated as a function of the density of the construction, the presence of wind, fire breaks (e.g., lakes, wide streets) and low fuel areas (e.g., parks, cemeteries). Suppression is calculated as a function of the available firefighting capabilities. The spread and suppression modules use a damage and loss function calculated from the essential facilities and lifelines modules to determine the response capabilities and effectiveness of the fire-fighting personnel. For debris, HAZUS methodology estimates 2 different types of debris. The first type is debris that fall in large pieces like steel members or reinforced concrete elements, which require special treatment to break into smaller pieces before they are hauled away. The second type is smaller debris more easily moved with bulldozers, such as brick, wood, glass, building contents, etc.

5. Direct Economic/Social Losses

Both direct and induced damage can lead to direct losses. There are 2 types of losses evaluated in the methodology: economic and social losses. The economic losses quantify the cost of repair and replacement of structures and lifeline systems that are damaged as a consequence of the earthquake. Structural and non-structural damage, as well as losses to contents inside buildings are included. To compute the direct economic losses, damage information from the direct damage module is combined with economic data of the study area, particularly construction/replacement cost of buildings and lifeline systems. Social losses are quantified in terms of casualties. To quantify the casualties, HAZUS methodology combines the output from the direct damage module with building inventory and population data. Estimations are carried out for two times of a day: 2:00PM (day time) and 2:00AM (night time).

6. Indirect Economic Losses

This module assesses the broad and long-term implications of the direct impacts (direct damage and losses) mentioned before. Examples of indirect economic impacts are changes in employment and personal income. This module is not included in this work due to a lack of complete data of income and employment.
3.3 BASE MAP AND DATABASE DEVELOPMENT

Spatial databases have been developed for the study cities and have been used as base maps to assist the hazard and vulnerability assessments. All important physical features of these cities are considered during the database development. Based upon the availability of existing data and information on the respective cities, an appropriate methodology was developed to acquire missing information by conducting physical feature surveys and attribute information collection.

For preparation of a base map, Satellite (Quickbird) images were collected. Ground Control Points for geo-referencing were selected at suitable locations in the image. Established bench marks like SOR, PWD, RWDB, and JICA were used as referencing point to do geo referencing. RTK-GPS and Total station were used for image geo-referencing. After geo-referencing of the image, physical features like road alignment, building outline, water body boundary, river boundary etc. were digitized. After completion of digitization, maps were printed for field verification. During field verification, a preset list of items was followed to collect attribute information against each of the digitized features. After completion of attribute information collection and feature verification, collected information had been added against the each surveyed features and base map was prepared for use. The steps followed during base map preparation are given in detail below.

Figure 12: Flow-chart of Base Map Development Process

Building Inventory Development

To properly assess the seismic vulnerability of existing building stock, it is necessary to know the building structural type, the building occupancy class, the number of building occupants during the day and the night, the total floor area, the number of stories, the cost of the building and its contents inside, the seismic vulnerability characteristics of building, etc.

To acquire the missing information, it is not necessary to survey each and every building in each of the cities—which is impossible under the scope of budget and time frame. Instead, a series of well-designed comprehensive building surveys have been carried out in this study. The surveys were classified into 3 levels: Level-01, Level-02, and Level-03 surveys.

Level 01: Building Survey

In the level 01 building survey, sidewalk and questionnaire surveys were carried out. The average time required for this survey by a 2-member team was about 8-10 minutes for one building. The building attributes collected at this survey level were:

- Number of stories
- Occupancy class
- Structural type
- Number of occupants during the day and the night (Based on no. of apartments)
- Age of the building (range)
- Presence of soft story (yes/no)
- Presence of heavy overhangs (yes/no)
- Shape of the building in plan view (rectangular, narrow rectangular, irregular)
- Shape of the building in elevation view (regular, setback, and narrow tall)
- Pounding possibility (yes/no)
- Building in slope land (yes/no)
- Visible ground settlement (yes/no)
- Presence of short columns (yes/no)
- Visible physical condition (poor/average/good)

Table 2 shows the list of number and types of buildings surveyed in the six cities.

Level 02: Building Survey

About 10 percent of the level 01 surveyed buildings were selected for the Level 02 survey on a random basis. In addition to the attributes acquired in the Level-1 survey, measurements of the building ground floor were taken. A sketch of the building plan at the ground story was made, and the dimensions of columns, concrete and masonry walls were measured. The main objective of this survey was to acquire more detailed information for more in-depth seismic vulnerability assessment of typical buildings. It took, on average, about two and a half hours for a 2-member team to complete the Level 02 survey on one building.

For concrete buildings, the building attributes acquired during the Level-2 survey are:

- Torsional irregularity (non-rectangular shape, unsymmetrical infill, unsymmetrical shear wall)
- Short column (less than 25% of floor height, 25-50% of floor height, more than 50% of floor height)
- Diaphragm discontinuity (mezzanine floor, floor opening)
- Slab system (cast in situ, pre-cast)
- Key dimensions (plan dimensions, typical column size, no. of bays, span length, shear wall dimensions)

For masonry buildings, the building attributes acquired during the Level 02 survey are:

- Wall Thickness
- Maximum unsupported length of wall
- Corner separation (yes/no)
- Anchorage of wall to floor (yes/no)
- Anchorage of roof with wall (yes/no)
- Wall to wall anchorage (yes/no)
- Bracing of flexible floor/roof (yes/no)
- Existence of gable wall (yes/no)
- Horizontal band (yes/no)
- Vertical post (yes/no)

Level 03: Building Survey

For dynamic measurement, level 03 surveys were conducted on few selected buildings in three of the cities. The main objective of this survey was to understand the behavior of different types of buildings during earthquake. For dynamic measurement of RCC Buildings, Micro tremor, Schmidt Hammer, Ferro Scanner and Vibration shaker were used. For masonry buildings, a shear strength test of the bonding mortar of masonry walls was conducted using a Hydraulic Jack with Deflection Meter.
Geotechnical and Geophysical Investigations

A number of geotechnical and geophysical investigations were conducted for preparation of engineering geological maps, soil liquefaction maps for seismic hazard assessment, and for damage and loss estimation. The investigations included boreholes with SPT, PS Logging, MASW and SSMM, Microtremor Array and Single Microtremor. Table 3 gives a brief description on the number and types of geotechnical and geophysical investigations conducted for the assessments:

Table 3: Description on the number and types of Geotechnical & Geophysical Investigations

</tbody>
</table>

The number of tests conducted had been determined depending on the surface geology (geomorphology) of the city. As a sample case, the Mymensingh town example has been provided in the following figure. The number of the tests was set in such a fashion that each of the geomorphic unit contains an adequate number of tests for the analysis.

Figure 14: Geological and Geophysical Investigations
All tests were conducted to measure the shear wave velocities at 30 m depth VS30 at the specific sites, which was utilized to comprehend the soil characteristics of the site. Peak Ground Acceleration at bed rock level was calculated from the source characteristics as well as the attenuation characteristics. Table 4 shows the empirical relationship between SPT N value and VS30.

The PGA will be amplified or de-amplified depending on the soil under the site. For the cities, the average shear wave velocities were calculated to illustrate the soil classification as shown in table 5. The soil has been classified according to table 5 as follows.

For most of the cities under the study, the soil class was either D or E, which corresponds to soft and very soft soil.

With the soil classification, the amplification maps for different cities can be derived as following figure (the example is given for Mymensingh Paurashava).

The distribution of PGA can be utilized to calculate the Liquefaction Probability of the soil, utilizing the liquefaction susceptibility of the site. The process is shown for Mymensingh Paurashava below:

Figure 18: Process of constructing liquefaction potential maps
3.4 Seismic Risk and Vulnerability Assessment

**Bogra Paurashava**

Bogra was founded as a town in 1850. Later, Bogra Paurashava was established in 1884. It consists of 21 wards and 46 mahallas with total area of 64.97 sq. km. The total population of the Paurashava is about 400,983 (male 53.20%, female 46.80%). The literacy rate among the town people is about 63%. The building occupancy of the city consists of Residential (84.21%), Commercial (10.07%), Educational (0.74%), Government Service (0.49%), Industrial (2.90%), Agriculture (1.15%) and Religious (0.44).

Young Flood Plain
- Active Channel: Broad, straight Chittagong channel with flowing water consist of sand
- Lateral Bar: Elongated active accumulation of sand along the bank of river consist of medium of fine sand

Old Flood Plain
- Depression: Irregular shaped deepest areas within the flood plain and flood basins having permanent water bodies consisting of sticky clay with organic matter
- Flood Basin: Irregular shaped deepest areas within the flood plain and flood basins having permanent water bodies consisting of sticky clay with organic matter
- Flood Plain: Broad flat areas extended from the river remained above normal flood level consisted of red to reddish brown colored silt and clayey soil
- Natural Levee: Irregular shaped accumulation of sediments along the bank and sloping away from either side towards the flood plain consists of silt and clay
- Point Bar: Crescent shaped accumulation of sand along the channel deposited at older flood plain
- Ox-bow Lake: Ox-bow-shaped body of water that formed by neck out of meander channels consist of sandy silt and sand

Rangpur City Corporation

Rangpur Paurashava was established in 1869 and upgraded as an “A” category Paurashava in 1986. It consists of 15 wards with total area of 39.5 sq. km. The total population of the Paurashava is about 294,265 (male 51.40%, female 48.62%). The literacy rate among the town people is about 72.1%. The building occupancy of the city consists of: Residential (84.59%), Commercial (9.83%), Educational (0.82%), Government Service (0.70%), Agriculture (1.24%), and Religious (0.64%). In 2013, the Paurashava was upgraded to City Corporation and divided into 33 wards. Area of the present city corporation with extended areas is 203.19 sq. km and population is about 10 Lac.

**Tangail Paurashava**

Tangail Paurashava was established in 1876. It consists of 18 wards and 63 mahallas with total area of 35.22 sq. km. The total population of the Paurashava is about 167412 (male 51.44%, female 48.56%). The literacy rate among the town people is about 71.8%. The building occupancy of the city consists of: Residential (88.85%), Commercial (6.63%), Educational (0.97%), Government Service (0.57%), Industrial (1.60%), Agriculture (0.03%), and Religious (0.08%).

**Structural type in Tangail Paurashava**

- Concrete: 45%
- Masonry: 34%
- CI Sheet: 17%

**Vulnerability factors in Tangail Paurashava**

- Soft Storey
- Heavy Overhang
- Short Column
- Pounding

4.1 Spatial Contingency Plans

Earthquake hazard risks need to be addressed in four phases: mitigation, preparedness, emergency response and recovery. However, an Earthquake Contingency Plan only addresses the emergency response management. The need for a comprehensive geo-hazard risk reduction “Contingency Planning” strategy that is linked to an easy implementation framework has been felt for quite some time now. It is therefore extremely important to anticipate, as best as possible, probable earthquake threats in the country particularly areas of high vulnerability such as the urban centers and plan for the quick and early recovery from potential earthquake emergencies.

As part of the Preparedness initiative, a Contingency Plan focusing on earthquake hazard has been prepared for different level for the study cities. In CDMP I, scenario-based Contingency Plans were prepared for National Level; City Level for the city corporations in Dhaka, Chittagong and Sylhet; and Agency Level Contingency Plans for the Department of Disaster Management (DDM), Armed Forces Division (AFD), Directorate General of Health Services (DGHS), Directorate of Relief and Rehabilitation (DRR), Fire Service and Civil Defense (FSCD), Titas Gas Transmission and Distribution Company Limited (TGTDCL), Bangladesh Telecommunication Company Limited (BTCL), Dhaka Power Distribution Company Limited (DPDC) and Dhaka Water Supply and Sewerage Authority (DWASA). During CDMP II, scenario-based Contingency Plans have been prepared at city level for the Cities of Bogra, Dinajpur, Mymensingh, Rajshahi, Rangpur and Tangail, and at Ward Level for Dhaka North City Corporation (13 Wards), Dhaka South City Corporation (12 Wards), Chittagong City Corporation (15 Wards) and Sylhet City Corporation (10 Wards). The plans have identified the evacuation routes, emergency shelter locations, and identified the gaps in the resource and needs by the responding agencies.
4.2 TRAININGS FOR PREPAREDNESS AT DIFFERENT LEVEL

Training, Advocacy and Awareness with regard to Earthquake

A good number of trainings were provided for different target groups across nine project cities during CDMP I and CDMP II. The main objectives of the training, advocacy and awareness-raising activities about earthquakes were to impart training, execute evacuation drills, and undertake advocacy and awareness campaigns in different cross-sections of the population, from the government officials to at-risk communities. Furthermore, decision makers and planners were educated on Contingency Plans and Seismic Hazard Maps. School children, teachers and religious leaders were made aware of the dangers of earthquake hazard, and masons were trained in constructing earthquake resistant buildings.

Up until March 2015, the following activities were conducted during CDMP I and CDMP II for increasing earthquake preparedness of the country:

- Training for decision makers and planners on Contingency Plan and Seismic Hazard Maps
- Safety and evacuation trainings for school children and teachers
- Training for religious leaders (imams) for awareness about earthquake dangers
- Training for masons and bar binders about earthquake safe construction practices
- Training for the managers/concerned officers of critical infrastructures on fire safety and evacuation
- Preparation of documentary to develop awareness of earthquake hazard and vulnerability
- Finally, production and dissemination of posters on earthquake vulnerability reduction measures.
4.3 Earthquake Simulation Drill

Earthquake simulation drills have been organized at community level in Dhaka North City Corporation, Chittagong City Corporation and Syret City Corporation areas. The main objective of the simulation drills was to validate the Ward-level Spatial Contingency Plan and assessing its effectiveness through participation of community and local level responsible agencies and stakeholders, so that they are more aware on how to use and execute the plan in a coordinated manner. At the same time, the drill also helped to raise community awareness about emergency preparedness activities during an earthquake.

The simulation drill in each selected ward was organized by the respective city corporations and led by the concerned ward councilor office/zonal office, with technical support from the study team. A simulation preparation committee was formed in each city, comprising representatives from different locally responsible first responder agencies, utility service agencies, and other ward level stakeholders as per the structure of Ward Disaster Management Committee proposed in the Contingency Plan. Each committee conducted several meetings to review the Contingency Plan, identify the simulation activities, select the community to be involved, identify the suitable site, and define the roles and responsibilities for simulation. Extensive ward level publicity to raise the community awareness as well as to ensure community participation in the simulation drills was made through a variety of audiovisual media such as leaflets, posters, banners, festoons, mixing, power point presentations, and one-to-one communication.
Conclusion

This atlas is limited to present the main findings of the Seismic Risk Assessment study. A good number of different studies under the current initiative of CDMP II have been carried out and reports are available at the e-library of CDMP (https://www.dmci.org.bd/e-library). The maps presented in this document can be used as a reference, for more detail it is recommended to consult the main reports.

The study team made an all-out effort in collecting the information necessary for this study. There were initiatives for primary data gathering in the case where there was data and information unavailability. However, in some cases it was not at all possible to get information from some of the government institutions due to their policy restrictions. In such cases, the study team decided to continue the study based on expert judgment in the respective areas.

Through year-long detailed investigation using state of the art technology, with relentless efforts by both national and international panel of experts, this study produced significant results. Research of this nature and scale is a first-time initiative in Bangladesh, therefore the findings from this study is very important for the decision makers in designing and implementing future Earthquake Preparedness Initiatives in the country.

Moreover, the maps developed under this study will be useful for development control to reduce earthquake risk in the respective cities and countries as a whole. The significant findings from the study are as follows:

- In general, at short return period, i.e. 43 years, the observed seismicity in and around Bangladesh controls the hazard for most considered structural periods.

- Ground motion across Bangladesh represented by PGA is in the range of 0.1-0.6 g, corresponding to the 475-year return period and in the range of 0.1-1.0 g, corresponding to the 2,475-year return period.

- The effect of high slip rate of Duaki fault could be observed as the largest seismic hazard in Bangladesh.

Among structural types of non-engineered building, BFL is the most common type in all the study cities. From the survey results, the age of buildings has been found to be related to structural types. For example, it was found that most buildings with concrete slab-column frames are constructed less than 10 years ago. On the other hand, most masonry buildings with concrete floors are more than 10 years old. Also, light reinforced concrete buildings were found to be older than reinforced concrete buildings.

Academic institutions at national and local level should take the initiative to carry out research aimed towards the further improvement and development of the earthquake hazard and risk maps for different cities and towns, and should also be given a task in transferring the knowledge through the establishment of professional courses on hazard and risk assessment.

The Government of Bangladesh and respective Paurashavas should take the initiative to incorporate disaster risk reduction into the urban development planning methodologies in all of the relevant sectors and relevant levels. The implementation of these guidelines in risk assessment and incorporation of hazard and risk information into spatial planning should be mandatory.

The respective Paurashavas and City Corporations involved in this study should continue using and update the database periodically. This will be helpful for the city authorities for initiating preparedness efforts for the city dwellers.

The GIS database and maps which have been used to generate the seismic hazard, vulnerability and risk maps in this Atlas should be kept on a web server and should be shared and updated by the respective agencies. Apart from this, local agencies should set up a data bank on Spatial Data Infrastructure, and define specific data formats and standards for collecting, storing, updating the database for further analysis.
ANNEX – 1 GLOSSARY OF TERMS

Acceleration
In physics, acceleration is used as the change of velocity with respect to time. Here we use the rate of change of velocity of a reference point. Commonly expressed as a fraction or percentage of the acceleration due to gravity (g) where g = 980 cm/s².

Active Fault
Fault is the offset of geological structure where one type of rock can be seen butting up against rock of another type. A fault that is considered likely to undergo renewed movement within a period of concern to humans is known as active fault. Faults are commonly considered to be active if they have moved one or more times in the last 10,000 years, but they may also be considered active when assessing the hazard for some applications even if movement has occurred in the last 500,000 years.

Asthenosphere
The highly viscous mechanically weak region is the upper mantle of the Earth. It lies below the lithosphere (crust and uppermost solid mantle), at depths between 80 and 200 km (50-124 miles) below the surface, but perhaps extending as deep as 400 km. Asthenosphere is generally solid although some of its regions could be melted; e.g. below mid-ocean ridge.

Aftershock
Secondary tremors that may follow the largest shock of an earthquake sequence. Such tremors can extend over a period of weeks, months, or years.

Most moderate to shallow earthquakes are followed by numerous earthquakes in the same vicinity. A big earthquake sometimes followed by an incredible number of aftershocks. Most aftershocks are located over the full area of the fault rupture, or along the fault plane or other faults within the volume affected by the strain associated with the main shock. The pattern of the aftershock helps confirm the size of area that slipped during the main shock.
Blind fault
A blind fault is a fault that does not rupture all the way up to the surface. So there is no evidence of it on the ground. It is buried under the upper most layers of the rock in the crust. It usually terminates upward in the axial region of an anticline. If its dip is less than 45 degrees, it is a blind thrust.

Casualties
Casualties estimates the number of people that will be injured and killed by the earthquake. The casualties are broken down into four severity levels that described the extent of injuries. According to HAZUS the casualty levels are described as follows:

- Severity level 1: Injuries will require medical attention but hospitalization is not needed.
- Severity level 2: Injuries will require hospitalization but are not considered life threatening.
- Severity level 3: Injuries will require hospitalization and can become life threatening if not promptly treated.
- Severity level 4: Victims are killed by the earthquake.

In the HAZUS analysis the casualty estimates are provided for two times of day: 2:00 AM and 2:00 PM. These times represent the periods of the day that different sectors of the community are at their peak occupancy loads. The 2:00 AM estimate considers that the residual occupancy loads are the maximum and the 2:00 PM estimate considers that the educational, commercial and industrial sector loads are maximum.

Crust
The crust is the outermost major layer of the Earth, ranging from about 10 to 65 km in thickness worldwide. The continental crust is about 40 km thick in the Pacific Northwest. The thickness of the oceanic crust in this region varies between about 10 and 15 km. The crust is characterized by P-wave velocities less than about 8 km/s. The uppermost 15-35 km of crust is brittle enough to produce earthquakes. The seismic crust is separated from the lower crust by the brittle ductile boundary.

Debris Generation
Debris generation estimates the amount of debris that will be generated by the earthquake. The debris is categorized in two sections: a) Brick/Wood and b) Reinforced Concrete/Steel. This distinction is made because of the different types of material handling equipment required to handle the debris.

Deep Earthquake
An earthquake whose focus is located more than 300 kilometers from the earth’s surface. Earthquake-report.com differs from the official notification, calling earthquakes with a depth of more than 100 km as “Deep”. This is mainly because of the non-damaging impact of these earthquakes. Of the total energy released in earthquakes, 3 percent comes from intermediate earthquakes.

Earthquake
Earthquake is any sudden shaking of the ground caused by the passage of seismic waves through the Earth’s rocks. Seismic waves are produced when some form of energy stored in the Earth’s crust is suddenly released, usually when masses of rock straining against one another suddenly fracture and slip.
Earthquake Risk

Earthquake risk is the probability that humans will incur loss or damage to their built environment if they are exposed to a seismic hazard. In other words, earthquake risk or seismic risk is an interaction between seismic hazard and vulnerability (humans or their built environment). In general, seismic risk can be expressed qualitatively as

$$\text{Seismic risk} = \text{seismic hazard} \times \text{vulnerability}$$

Fault Scarp

A fault scarp is a small step on the ground surface where one side of a fault has moved vertically with respect to another. It is the topographic expression of faulting attributed to the displacement of the land surface by movement along faults.

Fault Trace

Intersection of a fault with the ground surface; also, the line commonly plotted on geologic maps to represent a fault. It is more like intersection of fault with geological surface and leaving a mark.

Fire Following Earthquake

Damage to infrastructure after an earthquake is a major loss trigger. One of the consequences of such damage is fire following a seismic event. Fires often associated with broken electrical and gas lines, gas is set free as gas lines are broken and a single spark
can therefore trigger an inferno. To complicate things, water lines are broken and so there is no water to extinguish the fire. So an earthquake can not only trigger a fire by releasing combustible material, but also by impairing passive or active firefighting systems.

Ground Failure
An effect of seismic activity, such as an earthquake, where the ground becomes very soft due to the shaking, and acts like a liquid, causing landslides, liquefaction and lateral spreads.

Ground Motion (Shaking)
Ground motion is a term referring to the qualitative or quantitative aspects of movement of the Earth’s surface from earthquakes or explosions. Ground motion is produced by waves that are generated by sudden slip on a fault or sudden pressure at the explosive source and travel through the Earth and along its surface.

Intensity
The intensity is a number (written as a Roman numeral) describing the severity of an earthquake in terms of its effects on the earth’s surface and on humans and their structures. Several scales exist, but the ones most commonly used are the Modified Mercalli scale and the Rossi-Forel scale. The intensities of earthquake are measured, depending on location where it is needed to measure, unlike the magnitude, which is one number for each earthquake.

Intermediate Earthquake
An earthquake whose focus is located between 70 to 300 kilometers from the earth’s surface. Earthquake-report.com differs from the official notification calling earthquakes with a depth of more than 40 to 00 km as “Intermediate”. This is mainly because of the limited damaging impact of these earthquakes. Of the total energy released in earthquakes, 12 percent comes from intermediate earthquakes.

Liquefaction
The transformation of a granular material from a solid state into a liquefied state as a consequence of increased pore water pressures and reduced effective stress. In engineering seismology, it refers to the loss of soil strength as a result of an increase in pore pressure due to ground motion. This effect can be caused by earthquake shaking.

![Figure: 23: Soil Liquefaction](image)
Liquefaction occurs in saturated soils—that is, soils in which the space between individual particles is completely filled with water. This water exerts a pressure on the soil particles that influences how tightly the particles themselves are pressed together. Prior to an earthquake, the water pressure is relatively low. However, earthquake shaking can cause the water pressure to increase to the point where the soil particles can readily move with respect to each other.

When liquefaction occurs, the strength of the soil decreases and, the ability of a soil deposit to support foundations for buildings and bridges are reduced, as seen in the image below.

![Figure 24: Foundation Weakening Due to Soil Liquefaction in Adapazari, Turkey](image)

**Locked Fault**

A locked fault is a fault that is not slipping because frictional resistance on the fault is greater than the shear stress across the fault. Such faults may store strain for extended periods, which is eventually released in an earthquake when the frictional resistance is overcome. A locked fault condition contrasts with fault-creep conditions and an unlocked fault.

![Figure 25: Image courtesy of Geological Survey of Canada](image)

**Magnitude**

The magnitude is a number that characterizes the relative size of an earthquake. Magnitude is based on measurement of the maximum motion recorded by a seismograph (sometimes for earthquake waves of a particular frequency), corrected for attenuation to a standardized distance. Several scales have been defined, but the most commonly used are (1) local magnitude (ML), commonly referred to as Richter magnitude, (2) surface-wave magnitude (Ms), (3) body-wave magnitude (Mb), and (4) moment magnitude (Mw). ML, Ms and Mb have limited range and applicability and do not satisfactorily measure the size of the largest earthquakes. The moment magnitude (Mw) scale, based on the concept of seismic moment, is uniformly applicable to all
sizes of earthquakes but is more difficult to compute than the other types. In principal, all magnitude scales could be cross calibrated to yield the same value for any given earthquake, but this expectation has proven to be only approximately true, thus the need to specify the magnitude type as well as its value. An increase of one unit of magnitude represents a 10-fold increase in wave amplitude on a seismogram or approximately a 30-fold increase in the energy released. In other words, a magnitude 6.7 earthquake releases over 900 times (30 times 30) the energy of a 4.7 earthquake — or it takes about 900 magnitude 4.7 earthquakes to equal the energy released in a single 6.7 earthquake! There is neither beginning nor end to this scale.

However, rock mechanics seem to preclude earthquakes smaller than about 1 or larger than about 9.5. A magnitude -1.0 event releases about 900 times less energy than a magnitude 1.0 quake. Except in special circumstances, earthquakes below magnitude 2.5 are not generally felt by humans.

P Wave

P-waves are a type of body wave that is the first wave to arrive at the seismograph, and is called seismic waves in seismology. It can travel through a continuum. The continuum is made up of gases (as sound waves), liquids, or solids, including the earth. P-waves can be produced by earthquakes and recorded by seismographs. The name P wave is often said to stand either for primary wave, as it has the highest velocity and is therefore the first to be felt; or pressure wave, as it is formed from alternating compressions and rarefactions.

This compressive wave shakes the ground back and forth in the same direction and the opposite direction as the direction the wave is moving.

![Figure 26: Example of propagation of P-wave](image)

PGA

A small particle attached to the earth during an earthquake will be moved back and forth rather irregularly. This movement can be described by its changing position as its changing acceleration as a function of time. The peak ground acceleration is the maximum acceleration that a building or any structure situated at the ground at the time of an earthquake.

PGD

Peak ground displacement is the maximum horizontal distance a structure will move during the time of an earthquake.
**PGV**

An object attached to the earth during an earthquake will be shaken irregularly. This movement can be described by its changing position as its changing velocity as a function of time. The peak ground velocity is the maximum velocity that a building or a structure situated at the ground during the time of earthquake.

**Phase**

A stage in periodic motion, such as wave motion or the motion of an oscillator measured with respect to a point and expressed in angular measure. The change of seismic velocities within Earth, as well as the possibility of conversions between compressional (P) waves and shear (S) waves, results in many possible wave paths. Each path produces a separate seismic phase on seismograms.

**Plate**

The Earth's rocky outer crust solidified billions years ago. This crust is not a solid shell; it is broken up into huge thick plates. These relatively large rigid segments of the Earth's lithosphere move in relation to other plates over the asthenosphere.

**Plate Tectonics**

A theory supported by a wide range of evidence that considers the Earth's crust and upper mantle to be composed of several large, thin, relatively rigid plates. The temperature at the centre of the earth is as high 2500° C, while the upper surface is 25° C. There is also a huge amount of pressure in the inner mantle. This huge temperature and pressure causes the semiliquid material of inner mantle to move regularly. This causes the plates to move with respect to one another, and faults are created. Several styles of faults bound the plates, including thrust faults along which plate material is subducted or consumed in the mantle, oceanic spreading ridges along which new crustal material is produced, and transform faults that accommodate horizontal slip (strike slip) between adjoining plates.

![Figure 27: Major tectonic plates of the world](image_url)

**Normal and Reverse Fault**

Normal and Reverse fault are classified according to their relative movement to each other. In figure one there are two faults - the right one which is more like a foot, is named as footwall - and the other left one which is more like hanging or resting above the footwall is the hanging wall. When, due to gravity, the hanging wall moves downward with respect to footwall it is called normal fault (a). When the hanging wall moves upward with respect to footwall, it is called reverse fault (b).
Risk Assessment
A methodology to determine the nature and extent of risk by analyzing potential hazards and evaluating existing conditions of vulnerability that together could potentially harm exposed people, property, services, livelihoods and the environment on which they depend. Risk assessments (and associated risk mapping) include: a review of the technical characteristics of hazards such as their location, intensity, frequency and probability; the analysis of exposure and vulnerability including the physical social, health, economic and environmental dimensions; and the evaluation of the effectiveness of prevailing and alternative coping capacities in respect to likely risk scenarios. This series of activities is sometimes known as a risk analysis process.

Secondary Wave
A secondary wave is the second type of body wave other than P-wave that arrives in seismograph. It is called secondary wave because it arrives later than the P-wave, as it moves slower in the rock. It is also called shear or transverse wave, as it moves perpendicular to the direction of wave propagation. Unlike P-wave, the Secondary wave can travel only through the solid material and are not able to pass through liquids.

Seismic hazard study
Seismic hazard refers to the study of expected earthquake ground motions at the earth's surface, and its likely effects on existing natural conditions and man-made structures for public safety considerations; the results of such studies are published as seismic hazard maps, which identify the relative motion of different areas on a local, regional or national basis. With hazards thus
determined, their risks are assessed and included in such areas as building codes for standard buildings, designing larger buildings and infrastructure projects, land use planning and determining insurance rates.

**Seismic Waves**

Seismic waves are the result of an earthquake, explosion or volcano where sudden release of energy burst out in form of waves. During the energy release different type of seismic waves are created. There are body waves (P-wave and S-wave) which travel through the interior of the earth, and there are surface waves which travel through the surface of the earth.

**Seismicity**

The geographic and historical distribution of earthquakes. A term introduced by Gutenberg and Richter to describe quantitatively the space, time, and magnitude distribution of earthquake occurrences. Seismicity within a specific source zone or region is usually quantified in terms of a Gutenberg-Richter relationship.

**Shallow Earthquake**

An earthquake whose focus is located within 70 kilometers of the earth’s surface. Earthquake-report.com differs from the official notification calling earthquakes with a depth up to 40 km as “Shallow”. This is mainly because of the possible damaging impact of these earthquakes.

It is the shallow earthquake that are the most devastating, and they contribute about the three-quarters of the total energy released in the earthquake throughout the world.

**Spectral Acceleration**

Spectral acceleration (SA) is a unit measured in g (the acceleration due to Earth’s gravity, equivalent to g-force) that describes the maximum acceleration in an earthquake on an object (example structure) specifically a damped, harmonic oscillator moving in one physical dimension. This can be measured at (or specified for) different oscillation frequencies and with different degrees of damping, although 5% damping is commonly applied.

**Surface Faulting**

Displacement that reaches the Earth’s surface during slip along a fault. Commonly accompanies moderate and large earthquakes having focal depths less than 20 km. Surface faulting also may accompany aseismic tectonic creep or natural or man-induced subsidence.
