Introduction

Study prepared by IDIS "Viitorul" under the Moldova Energy and Biomass Project funded by the European Union, co-funded and implemented by UNDP Moldova

Biomass in Moldova is considered one of the most important sources of renewable energy. In general, we can say that biomass covers a wide range of materials, such as: agricultural and technical crops, agricultural and forestry residues, etc.

According to the definition provided in the European Directive 2003/30/EC, *biomass is the biodegradable fraction of products, waste and residues from agriculture, forestry, and industrial and municipal waste.*

In this context, it should be mentioned that biomass is the main fuel used in rural areas. As an agricultural country, the Republic of Moldova faces a major challenge - the use of its existing potential of biomass.

Since the objective of the study was to establish a top of districts according to the biomass potential from agricultural wastes, we would like to mention the fact that the results of the analysis reflect a more conservative scenario (pessimistic) for several reasons. Thus, calculations were performed with the available data, taken from the National Bureau of Statistics (NBS), for 2009 and 2010 regarding the surfaces of farms and peasant households in possession of agricultural land of at least 10 hectares. From this point of view, it is obvious that land areas which are less than 10 ha were not taken into consideration for the simple reason that there is no accurate statistics performed in this area. For these reasons, one can easily notice that there are considerable reserves which could increase the total biomass potential for production of briquettes and pellets.

According to the drafted methodology, at the first stage, we identified the biomass residues obtained after collecting agricultural crops, which were conventionally included in **Group 1** (wheat, barley, rye, oats, corn, sunflower, peas, rapeseed, soybean, buckwheat, beans and tobacco) or crops conventionally included in **Group 2** (vine, fruit trees, trees) that are usually pruned in the spring. At the second stage, these results were used to estimate the energy potential of biomass derived from above

mentioned crops by region and rayon for 2009 and 2010. Information that was used to make the necessary calculations, was taken exclusively from the NBS and was further processed by the authors involved in the research.

After analyzing the potential of biomass for each separate rayon at national level, a total potential of about **21,042 TJ** per year was obtained based on average values for 2009 and 2010. While comparing this result with domestic consumption of energy resources of the Republic of Moldova, which was about **92,544 TJ** in 2010, we found that 22% of total needs of energy resources can be covered by biomass. Moreover, this is a rather essential finding, given that the Republic of Moldova is 95% dependent on imported energy resources, therefore, theoretically, approximately 48% of natural gas imports could be reduced due to biomass resources, taking into consideration the fact that natural gas imports in 2010 amounted to about 43,295 TJ. These are key findings of the study prepared by experts of IDIS „Viitorul”.

In order to have an overview of the current potential of biomass by rayon and region, one can explore the “electronic map of the potential of biomass”, made on the basis of findings from this study: <http://www.biomasa.aee.md/potentialul-energetic-din-biomasa-total-pe-rm/>. Later on, it will be transferred on the web-site of the Agency for Energy Efficiency – www.aee.md

IDIS „Viitorul” extends its sincere appreciation to all the experts and companies that cooperated in the development of this study.

The study was contracted by Moldova Energy and Biomass Project to be used as an argument for piloting the briquetting business in Republic of Moldova.

Research methodology

In order to estimate the biomass potential of agricultural crops, it is necessary to estimate the amount of biomass residues obtained after collecting agricultural crops, which were conventionally included in **Group 1** (wheat, barley, rye, oats, corn, sunflower, peas, rapeseed, soybean, buckwheat, beans and tobacco) or crops conventionally included in **Group 2** (vine, fruit trees, trees) that are usually trimmed in the spring. To estimate the amount of agricultural residues and subsequent energy potential for agricultural crops in Group 1 and Group 2, we will use the following table:

Table 1.1. **Coefficients for production of dry matter (biomass), heat capacity and availability factor**

Crop	Biomass residue	Production of dry matter [^{1,2,3}]		Reference Heat Capacity [^{2,3,4}]	Availability factor [^{5,6}]		
		t/t of grain, t/ha (vineyards, orchards, forests)					
		Min	Max				
Wheat	Straw	1 [1]	1.8 [1]	14	25 [5]		
Barley	Straw	1.5 [1]	1.8 [1]	14	25 [5]		
Rye	Straw	1.8 [1]	2 [1]	14	25 [5]		
Oat	Straw	1.8 [1]	1.8 [1]	14	25 [5]		
Corn	Stalk + cob	1.2 [1]	2.5 [1]	14	65 [5]		
Sunflower	Stalk + hat	1.2 [1]	2.1 [1]	15	95 [5]		
Peas	Stalk	5 [1]	5 [1]	14	70		
Beans	Stalk	5 [1]	5 [1]	14	70		
Rapeseed	Straw	3.7 [1]	4 [1]	18	70		
Soybean	Straw	3.7 [1]	4 [1]	14	70 [6]		
Tobacco	Stalk	3 [2]	3 [2]	14	70		
Buckwheat	Straw	0.9 [1]	1.2 [1]	14	70		
Fruit trees	Branches	1.2 [1]	1.5 [1]	15	95 [5]		
Vine	Branches	0.8 [1]	1.1 [1]	15	97 [5]		

Note 1. References that were used to compile the table are shown in brackets.

Note 2. Conversion factors for forestry and wood processing residues can be found in Table 4.2

Comment 1. Reference heat capacity of straw is shown at humidity below 20%. Given that the heat capacity is shown for different levels of humidity in different sources, we will use conservative data approximated to whole numbers. The same is proposed for other types of biomass for which data taken from references relate to a certain level of humidity and the reference heat capacity values were estimated with a small reserve (by allowing for a higher humidity level) by rounding down to the whole number.

Comment 2. For straw derived from peas, rapeseed and buckwheat, the same availability factors are proposed for consideration as those for soybean, according to source [6].

Comment 3. According to statistical data (from NBS), information on residues from wood industry was collected, based on reports submitted by economic operators.

As shown in Table 1.1, in order to get biomass residues in tons per 1 ha of agricultural crops, for crops in **Group 1**, coefficients should be applied within the following range: K_1 t/t of grains – K_2 t/t of grains. While for crops in **Group 2**, in order to estimate the amount of residues in tons per 1 ha, coefficients will be applied within the following range: K_1 t/ha – K_2 t/ha.

Next, we will estimate the amount of biomass residues for two scenarios:

- a. *Scenario 1 min*, by applying the minimal coefficient K_1 ;
- b. *Scenario 2 max*, by applying the maximum coefficient K_2 .

Thus, if V is the area in hectares, then the following formula shall be applied: $V \times K_1$ and $V \times K_2$. After that, we will calculate the energy potential in TJ (Terajoule) for both scenarios. To this end, we will consider the value of the coefficient for the heat capacity shown in Table 1.1, which will be marked as R MJ/kg (Megajoule per kg) and we will take into account that $1\text{ TJ } 10^{-6} = 1\text{ MJ}$. It is obvious that $R\text{ MJ/kg} = R * 10^{-6}\text{ TJ/kg}$.

At the next step, since a part of residues is lost during collection, we will apply the availability factor marked as K_{disponib} .

Thus, given the availability factor K_{disponib} and factors K_1 and K_2 in order to determine the minimum and maximum amount of agricultural residues, which shall be marked as $K_{1,2}$, we obtain the following formula to estimate the energy potential of agricultural crops in Group 1:

$$(V \text{ ha} \times K_{1,2} \text{ t/t grains}) \times R * 10^{-6} \text{ TJ/kg} \times 1000 \text{ kg} \times K_{\text{disponib}}.$$

Similarly, we obtain the formula for estimating the energy potential of crops in Group 2:

$$(V \text{ ha} \times K_{1,2} \text{ t/ha}) \times R * 10^{-6} \text{ TJ/kg} \times 1000 \text{ kg} \times K_{\text{disponib}}.$$

Both formulas above cover the following relationship:

$$(V \times K_{1,2}) \times K_{\text{disponib}} \times R * 10^{-3} \text{ TJ}.$$

Thus, for each of these scenarios, we can estimate the energy potential in TJ, using the relations:

$$\text{Scenario 1 min: } (V \times K_1) \times R : 1000 \times K_{\text{disponib}}$$

and respectively

$$\text{Scenario 2 max: } (V \times K_2) \times R : 1000 \times K_{\text{disponib}}.$$

Next, we determined the average heat capacity for 2009 and 2010 respectively according to the relation:

$$\text{Caloric}_{\text{med}} \text{ 2009} = ((V \times K_1) \times R : 1000 \times K_{\text{disponib}} + (V \times K_2) \times R : 1000 \times K_{\text{disponib}}) : 2$$

$$\text{Caloric}_{\text{med}} \text{ 2010} = ((V \times K_1) \times R : 1000 \times K_{\text{disponib}} + (V \times K_2) \times R : 1000 \times K_{\text{disponib}}) : 2$$

At the last step, we determined the average values for 2009 and 2010, according to the formula:

$$\text{Caloric}_{\text{average}} = (\text{Caloric}_{\text{med}} \text{ 2009} + \text{Caloric}_{\text{med}} \text{ 2010}) : 2$$

The first four rayons were selected in each region while considering the data obtained, depending on the heat capacity.

Estimating the potential of biomass derived from bearing vineyards

According to official statistics, the total area of vineyards in the Republic of Moldova at national level in 2009 and 2010 was 149,000 ha and 145,000 ha, respectively, of which about 136,000 ha in 2009 and 133,000 ha in 2010 were bearing plantations. The National Bureau of Statistics keeps strict records of agricultural enterprises and peasant's (farmer's) households with agricultural land of 10 ha and more. In this context, according to the National Bureau of Statistics, the area of bearing vineyards, of agricultural enterprises and peasant's (farmer's) households with agricultural land of 10 ha and more was about 31,744 ha in 2009 and 29,638 ha in 2010.

In order to determine the potential of biomass derived from vineyards it is necessary to determine the residues obtained after pruning of vines. According to data from Table 1.1, to determine the production of residues in tons per 1 ha of bearing vineyards, both the minimal coefficient of 0.8 was applied for the Scenario 1 min, and maximal coefficient 1.1, for Scenario 2 max.

Thus, for each of these scenarios, we have the relations:

$$\text{Scenario 1 min: } (V \times 0.8) \times 15 : 1000 \times 0.97$$

and respectively

$$\text{Scenario 2 max: } (V \times 1.1) \times 15 : 1000 \times 0.97$$

where 15 MJ/kg is the coefficient for determining the reference caloric capacity, and 0.97 is the availability coefficient. After this, the average of caloric capacity for 2009 and 2010 was determined according to the relations:

$$\text{Caloric}_{\text{aver}} \text{ 2009} = ((V \times 0.8) \times 15 : 1000 \times 0.97 + (V \times 1.1) \times 15 : 1000 \times 0.97) : 2$$

$$\text{Caloric}_{\text{aver}} \text{ 2010} = ((V \times 0.8) \times 15 : 1000 \times 0.97 + (V \times 1.1) \times 15 : 1000 \times 0.97) : 2$$

And at the last phase the average for 2009 and 2010 was determined:

$$\text{Caloric}_{\text{aver}} = (\text{Caloric}_{\text{aver}} \text{ 2009} + \text{Caloric}_{\text{aver}} \text{ 2010}) : 2$$

Based on caloric capacity, the first 4 rayons form each region were selected and were included in the following table:

Table 2.1. General biomass potential derived from vineyards, of first 4 rayons from each region

Characteristics of biomass potential by regions

a. At national level

At national level, due to the fact that the total area of bearing plantations decreased from 149,000 ha in 2009 to 145,000 ha in 2010, according to the data of the National Bureau of Statistics, obviously the potential of biomass deriving from this type of biomass is also in decrease, from **1,879.86 TJ to 1,838.4 TJ**, approximately by 3%.

Thus, according to the NBS data, bearing plantations with the area of 10 ha and over of agricultural enterprise and peasants households decreased by 31,744 ha in 2009 to 29,638 ha in 2010. In these conditions, the biomass potential is decreasing by approximately 7% from **438.781 TJ to 409.7 TJ**.

b. At regional level according to the NBS data

Hereinafter, we will refer to bearing vineyards with area of 10 ha and over. In this context, there was also outlined a tendency of decrease in vineyard plantations with area of 10 ha and over in Northern, Central, Southern and ATU Gagauzia regions.

We note in Table 2.1 that the Southern region has the highest biomass potential - about 221.2 TJ. After it, the Central region with 99.8 TJ, and ATU Gagauzia Region follow with about 82.8 TJ, which indicates that the potential is approximately 2.22 and 2.67 times lower than the biomass potential of the Southern region. Biomass potential of Northern region is insignificant, about 6.52 TJ compared to the other regions.

If to refer to rayons within each region, according to data in Table 2.1, then 4 rayons from the Southern region, with the highest energy potential are identified: **Taraclia** (55.8 TJ), **Cahul** (48.9 TJ), **Cimislia** (27.28 TJ) and **Cantemir** (27.23 TJ). The rayons with the highest energy potential in the Central region, in a descending order, are: **Hinesti** (32.06 TJ), **Anenii-Noi** (20.88 TJ), **Ialoveni** (10.08 TJ) and **Calarasi** (7.81 TJ). In the Northern region we can mention the following rayons: **Singerei** (3.07 TJ), **Falesti** (1.67 TJ), **Floresti** (0.59 TJ) and **Glodeni** (0.55 TJ).

Energy potential of biomass derived from pruning of pome and stone fruit plantations

According to statistics, the Republic of Moldova has approximately 100 thousand hectares of fruit-bearing plantations with fruit trees and shrubs. Annually, these plantations generate huge amounts of agricultural residues, branches after annual pruning, which can be used for energy production. In order to identify the energy potential for each rayon separately, a more detailed analysis was performed. As reference, the official data of the National Bureau of Statistics were used, available for 2009-2010, separately by rayons, covering fruit-bearing plantations of pome fruits (apple, pear, quince and other trees) and stone fruits (plum, cherry, sweet cherry, apricots, peaches and other trees) of the agricultural enterprises and peasants households with agricultural land of 10 ha and over. Analysing the data, there were not taken into account data related to walnut plantations because they do not need pruning and the availability of the nutshell is very low as population uses it directly for combustion due to its high caloric capacity. Additionally, areas of fruit-bearing walnut plantations are quite small compared to other types of fruit trees. At the same time, it should be noted that during the latest years walnut plantations grew significantly, consequently during the next 8-10 years the availability of nutshell for energetic purposes will increase considerably. This hypothesis is confirmed by the statistics indicating an increase in the total planted area from 3,553 ha in 2009 to 4,430 ha in 2010, while the total area of bearing plantations in 2010 was only of 512 ha. Also, there were not taken into account the plantations of fruit shrubs which are present only in some rayons and have no interest because of very small areas, 182 ha in 2010.

For a more reasonable argumentation, there was performed a comparative analysis of results obtained according to NBS data with the data offered by the Ministry of Agriculture and Food Industry. This source has not been used as reference because the data were not confirmed for 2010 and for 2008 they were not significantly different compared to 2009.

Based on the calculation methodology there were used data about the area of fruit-bearing plantations and coefficients for determining the quantity of biomass (orchard branches as a result of annual pruning) according to source [1], these having values between 1.2-1.5 tons/ha. Because a part of branches obtained as a result of annual pruning of orchards may be used in other purposes, like direct combustion in the field in case of frost for more vulnerable varieties, and taking into account that reference analysis is made for plantations of agricultural enterprises and peasant households with agricultural land of 10 ha and more, the availability coefficient of 95% was used, as according to source [5]. In order to transform the volume of biomass into energetic units there is used a coefficient indicating the caloric capacity that can be obtained from one mass unit of dry material. This varies depending on the type of biomass and depending on its humidity. In case of orchard branches, to transform the available biomass quantity into energetic units the transformation coefficient 15 MJ/kg was used. This was selected according to sources [1,3,4] taking also into account the fact that humidity is less than 20%.

The energy potential was calculated for every rayon separately according to two scenarios, minimum and maximum, depending on the quantity of branches that can be obtained from one hectare of fruit-bearing plantations taking as reference the average area of fruit plantations for 2009 and 2010. To determine the top rayons that have the highest energy potential from biomass, the average between the minim and maxim energy potential was calculated. As a result, a total average energy potential by country of 659 TJ was obtained, details in Annex 3.1 and 3.2. Performing the same calculations based on data for 2009 of the Ministry of Agriculture and Food Industry we obtain an average energy potential of approximately 1,000.14 TJ, details in Annex 3.3. Based on the analysis performed according to NBS data, the region of the country with the highest potential of energy production from agricultural residues generated by fruit plantations was identified, this being the Northern region of the Republic of Moldova with a potential of approximately 361.26 TJ per year more than half of the total potential per country. Moreover, even the top first five rayons belong to the Northern region, Table 3.1.

Table 3.1. Top 5 Rayons by potential of energy from orchards

The obtained results were compared with data for 2009, after both sources, for the first rayons with the highest energy potential. As a result, classification of the first 4 positions for Central and Southern regions calculated according to the National Bureau of Statistics (BNS) data coincides with the results of calculations performed based on data offered by the ministry (Annex 3.1, 3.2 and 3.3). In case of the Northern regions, the results coincide only for position 1 and 4. Comparing the 2009 classification with that for 2010, obtained according to the National Bureau of Statistics data, you can notice that the classification is not maintained for any of the top 10 positions, reason for which the data used as reference were calculated as the arithmetic average for results obtained separately for 2009 and 2010.

Potential of biomass derived from forestry and wood processing residues

Forest areas of the Republic of Moldova are important and strategic natural resources for development of national economy, and they represent an important reserve for the energetic sector. Forest resources require a comprehensive and unified management in close relation with other natural resources. Responsible for management of forest resources in the Republic of Moldova is currently the "Moldsilva" Agency. In case there is a prudent and rational management, Moldova's forests can offer significant and constant energetic benefits. Forestry sector provides the national economy about 400 thousand m³ of timber harvested in the process of complex forestry works (works of care and management, regeneration, conservation, ecological reconstruction, pruning etc.). As a result of these works, which do not have the intention to obtain biomass-based energy resources, important quantities of raw material are obtained for production of fuel in form of briquettes. According to estimations, vital needs of rural population (house heating, cooking meals etc.) are met up to a share of 70% by wood products. Every year, the forestry sector brings an income to the national economy of 0.5-0.6% of the Gross Domestic Product.

All forest renewal and harvesting works are performed by "Silva" Agency. Timber is harvested in the forests of the Republic of Moldova, according to Article 33-36 of the Forestry Code, by cutting by-products (first cleaning, pruning, selective cuttings, hygiene cuttings), cutting of main products (regeneration, conservation, hygiene clean cuttings) and ecological reconstruction. As a result of these works during 1997-2010 big volumes of timber were collected. These volumes are shown in Table 1. During 1997 – 2010 there were 5.787 million m³ of timber, among which 586.1 thousand m³ of wood for industrial processing, 4,812.3 thousand m³ of firewood.

Table 4.1. Volume of timber harvested in the forestry fund managed by "Moldsilva" Agency

No.	Reference years	Volume of harvested timber, thousand m ³			including:	
		Total	Including sold volume	Industrial wood	firewood (including twigs, branches, limbs)

Source: "Moldsilva" Agency

It should be noted that annual production of respective volumes does not affect the status of forestry fund. Timber collected by forestry enterprises in Moldova's forests during a year is sold to population, economic operators and/or is processed directly within specialized sections of forestry enterprises. Forestry has approximately 30 sections of different capacities for wood cutting and processing, as well as drying installations. Forestry enterprises process an annual average volume of about 25 thousand m³ of timber. Low efficiency of using the production capacity is influenced by the low quality of raw material, limited demand for processed timber and low purchasing capacity of population of the Republic of Moldova. The range of products, obtained from wood processing includes parquet, timber, cut semi-finished materials, fence strips, charcoal and others.

It should be taken into account that residues obtained as a result of wood processing are sold for household needs and as **fuel to population and other consumers**. In order to assess the potential of biomass derived from forest resources the following steps have been undertaken.

Methodological clarifications

The statistical data were collected from ALRC, National Bureau of Statistics, and "Moldsilva" Agency. Total forest areas were assessed for the country and by regions, rayons, including ATU Gagauzia.

According to statistics presented by the Agency for Land Relations and Cadastre of the Republic of Moldova (ALRC) in 2009 the total area of forests was 423,979.9 ha, in 2010 – 393,020.34 ha, respectively. The richest region in forests in the Republic of Moldova is the Central region, which in 2010 had an area of 193,784.97 ha. In terms of regional structure, the largest areas covered by forests in the Northern region in 2010 are rayons Falesti and Singerei with 12,060.39 ha and 11,636.97 ha, respectively, in Central region – rayons Hincesti and Straseni, respectively with 38,674.11 ha and 26,726.22 ha, Southern region - in Cahul and Cimișlia rayons with 18,048.68 ha and 12,862.35 ha respectively, and the area covered by forests in ATU Gagauzia is 17,779.77 ha.

The volumes of products obtained from forest cutting were distributed according to the data provided by "Moldsilva" Agency for 2009 and 2010. As a result of harvesting forest wood, a large amount of branches and rods of different size and thickness and different chips is obtained. The coefficient of residues obtained from one *ha* of forest (branches, rods, etc.) for 2009 and 2010 was determined.

For 2009, the relation $C_1=V_1/S_1$ was used,

where C_1 is the coefficient of residues obtained from one *ha* of forest, V_1 is the volume of branches and rods obtained and S_1 is the total area covered with forests and forest strips in 2009

For 2010 the relation $C_2=V_2/S_2$ was used,

where C_2 is the coefficient of residues obtained to one *ha* of forest, where V_2 is the volume of branches and rods obtained and S_2 is the total area covered with forests and forest strips in 2010.

Table 4.2 Conversion coefficients for forestry and wood processing residues

Biomass residue	Conversion ha to m ³		Conversion m ³ to tons	Caloric capacity, MJ/kg	Availability factor
	2009	2010			
Wood branches, rods	0.145	0.172	0.4 [7]	15 [1]	90 [8]
Residues from wood processing industry	-	-	-	15 [3]	90 [8]

Thus, the coefficient for obtaining residues from forests was for 2009: $C_1=0,145$, and, respectively, for 2010: $C_2=0,172$.

Using calculated coefficients, we assessed the volume of biomass, in cubic meters, that can be used for briquetting. We used in our study coefficients of energy potential for measurement units MJ per kilogram of dry wood. Therefore, it was necessary to transform the volume of cubic meters of dry forest derived biomass in mass measurement units (tons). Thus, the amounts of residues in tons were calculated for every rayon. In order to assess the volume of biomass in these residues, coefficient for transformation of branches and rods from cubic metres into tons $M = 0.4$ was taken into consideration, expressing dry mass of residues in tons to one cubic metre of residues (see Table 4.2).

According to 2009 evaluation, a total of 24,590.83 tons, amount of forest dry biomass, and 27,039.79 tons, respectively in 2010, were obtained in the Republic of Moldova. In terms of regional structure, the classification was distributed as follows: in 2009, the first place in the Central region was 12,226.28 tons, followed by Northern region - with 5,675.21 tons, South - with 5,159.02 tons and ATU Gagauzia with 1,036.0 tons. Classification for 2010 is the following: the first place in the Central region was 13,332.4 tons, followed by North - with 6,517.87 tons, South - with 5,369.28 tons and ATU Gagauzia - with 1,223.24 tons.

In rayon structure, the classification by volume of dry biomass for 2009 is the following (see Annex 4.1):

North – the first is Falesti rayon, followed by Glodeni, Singerei, Riscani.

Centre – the first is Hincesti rayon, followed by Straseni, Orhei, Calarasi.

South – the first is Cahul, followed by Causeni, Cantemir, Cimislia.

ATUG

In rayon structure, the classification by volume of forest dry biomass for 2010 is the following (see Annex 4.2):

North – the first is Falesti rayon, followed by Singerei, Glodeni, Soroca.

Centre – the first is Hincesti rayon, followed by Straseni, Orhei, Calarasi.

South – the first is Cahul, followed by Causeni, Cantemir, Cimislia.

ATUG

According to data provided by the National Bureau of Statistics (BNS), every year in the Republic of Moldova residues are obtained from the processing industry of imported wood, domestic forest wood, furniture production and from other enterprises producing wooden items. This volume is an important one to be taken into account when assessing the biomass volume for energetic purposes. From the experience of manufacturers, and also taking into account surveys on biomass assessment for energetic purposes it was found out that residues have a certain degree of use for this purpose. To this volume of residues, $K_l=0.9$, the share of availability of wooden residues is applied. According to results of focus groups, which discussed the availability of using residues obtained as a result of wood processing, according to some surveys, it was decided to use the coefficient of availability of wooden residues $K_l=0.9$. After assessing the volume of biomass derived from wooden residues and wood harvest derivates by each rayon separately, the energy potential coefficients were applied to these two types of biomass.

For residues obtained from wood processing for industrial purposes and, respectively, for timber (derivates from the harvested forest wood) the coefficient $K_e=15MJ/kg$ was applied.

This way, we assessed the total energy potential of dry biomass for the Republic of Moldova, by regions and by rayons, for 2009 and 2010.

After assessing the energy potential for these two types of biomass for 2009 and 2010 respectively, the average for both years was calculated for the country level, by regions and by all rayons (see Annexes 4.1 and 4.2).

As a result of assessing the energy potential for this type of dry biomass the regions and rayons were classified based on the volume of energy potential. Classification by regions and rayons is provided in Table 4.3.

In total, the country's energy potential for this type of biomass was 463.64 TJ for 2009 and 505.42 TJ for 2010. Classification by regions is the same for both years 2009 and 2010 without changes and it is the following – first place Centre, followed by North, South, ATUG.

Potential of biomass derived from residues of pulses, oilseeds and technical crops

In order to determine the biomass potential, there were included in the category of pulses, oilseeds and technical crops, the crops with the highest production potential in the Republic of Moldova, from those categories, according to NBS data: sunflower, soybeans, rapeseed, dry peas, beans and tobacco. Hereinafter, by notion of pulses, oilseeds and technical crops, we will refer to the above mentioned crops.

Methodological clarifications: In order to determine the energy potential of crops from pulses, oilseeds and technical crops group we used the statistical data of the National Bureau of Statistics (NBS) for 2009 and 2010, by territory (rayon). Being aware of the constraints in using those data for calculation of total biomass potential (National Bureau of Statistics is recording by territory only the data for categories of agricultural units "agricultural enterprises" and "peasant households" with agricultural area exceeding 10 ha), we tried to identify data as complete as possible with regard to production of those crops. Such data have been identified at the Ministry of Agriculture and Food Industry (MAFI), however only for sunflower and only for 2008 and 2009. Information from the MAFI contains data about sunflower production in areas larger by 28% than those stated by the NBS data. However, taking into account that the main goal of this research is to identify classification of rayons from the 3 regions by biomass potential and to assure data comparison, we, hereinafter, used the NBS data for calculations. The statistical data coverage does not affect, in the end, classification of rayons within each region by their potential. It may be, however, influenced significantly by years used for calculations, taking into account the very big differences in crop yields depending on weather conditions in each year and crop rotation. MAFI data may be used only to determine the absolute biomass potential per each rayon, maintaining the same period of comparison for all the crops. At the same time, taking into account the fact that most of the crops in the respective group are cultivated by agricultural enterprises and peasant households with area of more than 10 ha, the differences

between data by territory and total data for all categories of enterprises can not modify significantly rayons' classification or increase the differences higher than 21-26% in the total potential of the respective crops. Thus, for example, comparing total production of sunflower by territory for household categories "agricultural enterprises" and "peasant households with areas of more than 10 ha", recorded by the NBS, with total production of sunflower at country level for all categories of households (from NBS Statistical Yearbook), we get a "coverage" of 79% for the data we used in our calculations. This coverage is 74% for soybeans.

Total energy potential of pulses, oilseeds and technical crops, as biomass for briquettes production for 2009-2010 is approximately 10,577.3 TJ (minimum estimates), 14,451.1 TJ (maximum estimates), 12,514.2 TJ (average estimates). Among crops included in the respective group, the greatest potential (according to average estimates) of 51% is that of sunflower, followed by rapeseed - 22%, soybeans - 20%, dry peas - 6%, tobacco - 1% and beans- 0.1%. Separately, data by territory for each crop from the respective group are provided in Annexes 5.1-5.6.

At regional level, the highest energy potential of these crops is registered in the Northern region - 7,127,0 TJ (average potential), or 58% of the total potential. Then the Southern region follows, with an average potential of 2,678.1 TJ, or 21% of the total potential. Central region has a potential of 1,821.2 TJ, average estimations, or 15% of the total potential. The assessed average potential for ATU Gagauzia, for 2009-2010, is 773.0 TJ, or 6% of the total potential (Table 5.1).

At rayon level: 1) Northern region – classification is dominated by Drochia rayon, with an estimated average potential of 964.2 TJ and Riscani, with 948.0 TJ. The following positions are held by rayons Edinet - 825.3 TJ and Soroca - 704.1 TJ.

2) Southern region – on the first position according to pulses, oilseeds and technical crop potential in this region is Stefan Voda rayon, with an estimated average potential of 592.9 TJ, followed by Cahul rayon, with 427.1 TJ, Causeni - 372.1 TJ and Cantemir - 339.8 TJ.

3) Central region – Biomass energy potential from pulses, oilseeds and technical crop potential is dominated by Ungheni rayon, with an average potential of 256,5 TJ, followed by rayons Orhei - with 251.9 TJ, Soldanesti - with 244.0 TJ and Rezina - with 229.8 TJ.

Source: Prepared based on NBS data

Sunflower: As mentioned above, this crop has the highest energy potential within the respective group of crops. This is approximately 4,626.8 TJ (minimum) and 8,096.9 TJ (maximum), or between 44%-56% of the total potential of all crops in the respective group. The highest potential of this crop was identified in the Northern rayons: Drochia (from 377.4 TJ up to 660.5 TJ) and Soroca (from 300.1 TJ up to 525.1 TJ). The potential of sunflower as biomass energy varies in Floresti rayon from 294.5 TJ up to 515.4 TJ (3rd place among Northern rayons) and Riscani rayon from 272.7 TJ up to 477.2 TJ (4th place) (Annex 5.1). In Southern rayons, the highest potential of this crop was identified in Stefan Voda rayon (from 209.2 TJ up to 366.1 TJ) and Cahul rayon (from 154.0 TJ up to 269.5 TJ). Then follow: Causeni rayon (from 123.9 TJ up to 216.7 TJ) and Cantemir rayon (from 108.1 TJ up to 189.1 TJ). The highest potential

of sunflower in the Central region was identified in Ungheni rayon (from 143.3 TJ up to 250.7 TJ) and Orhei rayon (from 119.5 TJ up to 209,1 TJ). Soldanesti rayon (3rd place) has an approximated potential from 118.3 TJ up to 207.1 TJ, and Rezina rayon (4th place), from 110.1 TJ up to 192.6 TJ.

Total energy potential of sunflower, according to MAFI data, differs from those presented above by 22%, on the account of larger areas, reflected in these data. However, we should bear in mind the season factor, given the fact that when determining sunflower energy potential according to MAFI data, we used years of 2008 and 2009. According to these data, the highest potential of sunflower in the Northern region is, like in the case of NBS data, in Drochia rayon, followed by Floresti (3rd place according to NBS data), Riscani (4th place, according to NBS data) and Soroca (2nd place, according to NBS data). Classification in Southern region, like in the case NBS data, is dominated by rayons Stefan Voda and Cahul, followed by Cantemir (6th place, according to NBS) and Taraclia (5th place, according to NBS). In the Centre region, on the first place, as in the case NBS data, is situated Ungheni rayon, followed by Soldanesti (3rd place, according to NBS), Orhei (2nd place, according to NBS) and Telenesti (5th place, according to NBS) (Table 5.2).

Source: Prepared based on MAFI data

Rapeseed: The respective crop was identified as the second crop in terms of its potential from the respective group of crops. Total energy potential of rapeseed was determined to about 5,950.6 TJ (minimum potential) and 6,3542.2 TJ (maximum potential). However, the territorial distribution of this crop is extremely uneven, with the highest quantity grown in the Northern (about 44%) and Southern regions (without ATU Gagauzia) (about 36%), and insignificant quantity grown in the Central region (10%) and ATU Gagauzia (9%). The highest potential of this crop in the Northern region was identified in Drochia (from 220.9 TJ up to 238.9 TJ) and Riscani rayons (from 169.0 TJ up to 182.8 TJ), followed by Soroca (from 135.3 TJ up to 146.3 TJ) and Glodeni (from 126.0 TJ up to 136.2 TJ) (Annex 5.2). The highest potential of rapeseed in the Southern region was identified in Stefan Voda (from 205.4 TJ up to 222.1 TJ) and Cahul (from 150.2 TJ up to 162.4 TJ) rayons, followed by Causeni (144.8-156.5 TJ) and Cantemir (125.1-135.2 TJ) rayons. The highest potential of rapeseed in the Central rayons is found in Ungheni and Orhei rayons (by 40-43 TJ each). Rapeseed potential in ATU Gagauzia is between 246.4 TJ and 266.3 TJ.

Soybeans: The third crop in terms of biomass energy potential in the respective group is soybean. Its residues are extremely appreciated by local producers as biomass for briquettes. Total potential of this crop was determined to be about 2,359.4 TJ (minimum) and about 2,550.7 TJ (maximum). However, this is concentrated almost exclusively in the Northern region (98%), with insignificant quantities in the Centre and South. Rayons with highest soybean potential are Edinet (443.1-479.0 TJ) and Riscani (349.9-378.3 TJ), followed by Briceni (335.4-362.6 TJ) and Ocnita (306.3-331.2 TJ) (Annex 5.3).

Dry peas, beans, tobacco: The potential of the other crops in the respective group is much lower than that of 3 crops mentioned above (only about 7% of group's total potential). Distribution of this potential by rayons is shown in Annexes 5.4-5.6.

Estimating the energy potential of biomass derived from grain crops

In order to assess the energy potential generated from biomass of grain crops the following agricultural crops were taken into consideration: wheat, barley, oats, rye and buckwheat. Corn, one of the most important suppliers of biomass, is assessed separately.

At national level, the total annual average volume of energy, measures in TJ, in 2009-2010 was 3,925. Crops with the highest energy potential are: wheat – 2,857 TJ (representing 73%) and barley – 1,049 (representing 27%). The other crops analysed had insignificant contributions.

To note in this context is that these results were obtained based on processing NBS information on areas and harvest of agricultural farms with more than 10 ha during 2009-2010.

Taking into account incompleteness of this database, we also processed the available information from the Ministry of Agriculture and Food Industry (MAFI) for the period 2008-2009, although in this case there were analysed only 3 types of crops: wheat, barley and corn. The processed information included in Annexes.

According to MAFI information, in 2008-2009 the average annual value of energy potential related to the first 2 crops: wheat and barley was of 6,864 TJ, which is almost 1.8 times higher compared to calculations performed based on NBS information.

Large discrepancy in the results of calculations, caused by use of these 2 data sources may be explained first of all by the coverage of corn producers in the statistical evidence: thus, NBS provides information on production of wheat for an area of 258,094 ha (2009) and 253,585 (2010), while MAFI information covers an area of 408,709 (2008) and 346,798 (2009). Areas considered by NBS for corn are: 62,846 (2009) and 77,393 (2010), and those included in MAFI statistics – 421,810 (2008) and 393,525 (2009).

At regional level, if we consider information of the NBS, the most rich in energy potential based on grain biomass is the Northern region (1,754 TJ or 45%) followed by Southern region (1,056 TJ or 27%).

Processing MAFI information allowed identifying the same regions.

At rayon level, based on the information from NBS, the ranking of rayons within regions is as follows:

- in the Northern region: 1st position is held by Drochia rayon, followed by Floresti, Falesti and Soroca;
- in the Central region: 1st position is held by Ungheni, followed by Anenii Noi, Orhei and Hincesti;
- in Southern region: 1st position is held by Stefan Voda, followed by Causeni, Cahul and Taraclia;
- potential of the ATU Gagauzia is 323 TJ, representing 8% of the total.

Assessment of energy potential from corn biomass

During 2009-2010, according to the NBS information, the energy potential of corn biomass was **3,035 TJ**, which represents 77% of grain crops potential.

At the same time, if we use MAFI information, we obtain an energy potential of **22,221 TJ**, which exceeds over 7 times the figure calculated based on NBS data. This large discrepancy may be explained, as mentioned above, through the corn producers' coverage in the statistical evidence.

GAGAUZIA ATU	20,97	773,00	82,80	15,62	287,92	322,89	1503,20	

As shown in the table above, the top position in terms of biomass potential is held by the North region, which account for 10647.63 TJ, followed by South (5034.40 TJ) and Centre (3744.76 TJ).

The breakdown by rayon is shown in Table 7.2. below.

Table 7.2. The first four rayons in each region with the greatest biomass energy potential

Position	Total biomass energy potential, TJ					
	North		Centre		South	
1	Drochia	1420,63	Ungheni	538,42	Stefan Voda	1056,30
2	Rascani	1331,34	Orhei	438,61	Cahul	880,87
3	Edinet	1083,46	Hancesti	426,71	Causeni	679,99
4	Floresti	1077,95	Soldanesti	405,65	Taradia	665,74

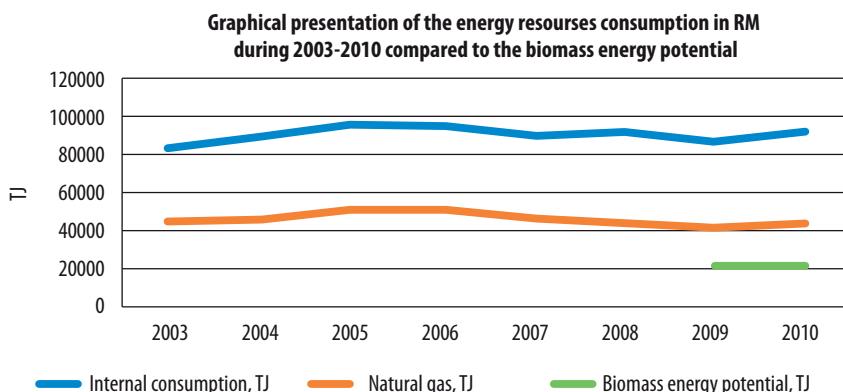

Source: calculated based on the information from NBS

As shown in Table 7.2, Drochia rayon has the greatest potential of biomass at the rayon level (1420 TJ), followed by Stefan-Voda rayon (1056.30 TJ) and Ungheni rayon (538.42 TJ).

About 48% of natural gas imports could be reduced due to biomass resources

After analysing the potential of biomass for each separate rayon, a total potential of about 21,042 TJ per year was obtained based on average values for 2009 and 2010. While comparing this result with domestic consumption of energy resources of the Republic of Moldova, which was about 92,544 TJ in 2010, we found that 22% of total needs of energy resources can be covered by biomass.

Chart 8.1. Consumption of energy resources compared to potential of biomass-based energy for period 2009-2010

Source: Calculated based on the information from NBS

Text Box: Graphical representation of energy resources in the Republic of Moldova during 2003-2010 compared to biomass-based energy potential

Moreover, this is a rather essential finding, given that the Republic of Moldova is 95% dependent on imported energy resources. Therefore, approximately 48% of natural gas imports could be reduced due to biomass resources, natural gas imports in 2010 amounted to approximately 43,295 TJ.

Conclusions and recommendations

Because the main objective of the study was to identify the top rayons by the biomass potential, the analysis results show a more conservative/pessimist scenario due to several reasons. Below, from the point of view of experts of IDIS "Viitorul", it will be highlighted the most important problems and the possible solutions related to the assessment of energy potential of biomass from crops and measures referring to the growth of the briquettes and pellets production at national level. Thus:

1. There were performed calculations with the available data for 2009 and 2010 regarding areas of the agricultural enterprises and peasant households with agricultural land of 10 ha and more. From the examples highlighted above it can be clearly noticed that the statistics of the NBS differs in many situations from the statistics of the Ministry of Agricultural and Food Industry. From this point of view, it can be easily noticed that there are considerable resources in terms of increasing the total biomass potential for briquettes production.
2. Another important reserve for increasing the final potential is the residues and the availability coefficients used, especially for grain crops, which can be greatly improved with the help of some governmental policies focused on this issue and in the context of building new biofuel market.
3. Expenditures for reducing household heating belong also to current practices of biomass use, the population in this sense being accustomed to use it in its primary form which is less efficient. From this point of view, briquetting and the improvement of combustion technologies would allow cutting expenses for household heating.
4. It is to be mentioned that residues of the most important cultivated crops were taken into account, while significant quantities of biomass can also be obtained from other types of plants and non-agricultural crops as thicket, wild bushes, energetic plants and many other cultures that grow in the meadow areas, bottom land etc.
5. The data regarding walnut plantations were not taken into account in this research, because their areas are very small and the nut trees

do not need pruning, however, these plantations will have an increasing interest for the nutshell in 8-10 years due to the growing areas of walnut plantations. The statistical data show an increase in the total area of walnut plantations from 3,553 ha in 2009 to 4,430 in 2010, while the total area of bearing plantations for 2010 was only 512 ha.

6. In order to determine the absolute potential of biomass for the production of briquettes/pellets, in the absence of complete statistical data, it is recommended to use the data of the agricultural census conducted in 2011. The census results were not available (processed by NBS) yet at the time this study was conducted.
7. According to the calculations made, each of the reviewed region: North (10,647.63 TJ), Centre (3,744.76 TJ), South (5,034.40 TJ) and ATU Gagauzia (1,503.20 TJ), has the necessary and sufficient local biomass potential to launch profitable businesses in the field of briquettes and pellets production, using the raw material (raw materials) predominant in that area.
8. The first 4 rayons from each region, with the highest biomass energy potential can be identified in the Table below:

Place	Total biomass energy potential, TJ					
	North		Centre		South	
1	Drochia	1,420.63	Ungheni	538.42	Stefan Voda	1,056.30
2	Riscani	1,331.34	Orhei	438.61	Cahul	880.87
3	Edinet	1,083.46	Hinesti	426.71	Causeni	679.99
4	Floresti	1,077.95	Soldanesti	405.65	Taraclia	665.74

Source: calculated by IDIS "Viitorul" based on the information from NBS

1. After analysing the potential of biomass for each separate rayon, at national level, a total potential of about **21,042 TJ** per year was obtained based on average values for 2009 and 2010. While comparing this result with domestic consumption of energy resources of the Republic of Moldova, which was about **92,544 TJ** in 2010, we found that 22% of total needs of energy resources can be covered by biomass. Moreover, this conclusion is a rather essential finding, given that the Republic of Moldova is 95% dependent on imported

energy resources, thus we could certainly affirm that the energy sources of biomass equals, at least to the energy potential of approximately 48% of natural gas imports, if we take into consideration the fact that the natural gas imports in 2010 amounted to 43,295 TJ.

2. It is necessary that the NBS revises the methodology for collection of data and information on agricultural crops, as well as their structure in order to keep the total real evidence of real areas of agricultural plantations which represent the most important resources of local biomass. In this sense, it would be useful to maintain and publish separately data on residues of agricultural crops that can be used as renewable energy sources.
3. According to interviews conducted with producers and according to survey results, conducted countrywide, we found that people do not have sufficient knowledge about biomass and its advantages. Respectively, it is proposed to intensify the actions for public/decision-makers information with regard to possibilities of using alternative energy sources, especially biomass to produce energy in a comfortable way.
4. Taking into account that production of briquettes and pellets is not regulated by law it is recommended to adopt a law to provide for all the biomass types that can be largely used (or prohibited), rules and norms for production and distribution activity.
5. Since the Republic of Moldova does not have national standards in place that would include technological norms, quality requirements, calorie limits for each type of product etc., it is recommended to develop regulatory norms in this sense, so that each producer of briquettes and pellets to comply with technical norms and quality standards.
6. For state's energetic security, the survey revealed the need to amend some legislative documents related to fiscal legislation, with the help of which manufacturers of biomass production would get tax facilities on imported technology, equipment and machinery, which would reduce the production costs.

7. In order to attract investments in briquettes and pellets production, and to facilitate initiating businesses in this area an income tax relief, for example, for a period of 3 years and a reduction of up to 50% of the invested resources after the initial three years of activity.
8. In order to access funding for the potential producers it is required to develop programs to support business in the area of briquettes and pellets production, including use of the Program to attract remittances in the economy - PARE 1 +1.
